(54) Title: ENCAPSIDATED RECOMBINANT POLIOVIRUS NUCLEIC ACID		
(57) Abstract		
<p>The present invention pertains to a method of encapsidating a recombinant poliovirus nucleic acid to obtain a yield of encapsidated viruses which substantially comprises encapsidated recombinant poliovirus nucleic acid. The method of encapsidating a recombinant poliovirus nucleic acid includes contacting a host cell with a recombinant poliovirus nucleic acid which lacks the nucleotide sequence encoding at least a portion of a protein necessary for encapsidation and an expression vector comprising a nucleic acid which encodes at least a portion of one protein necessary for encapsidation under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the expression vector into the host cell and obtaining a yield of encapsidated viruses which substantially comprises an encapsidated recombinant poliovirus nucleic acid. A foreign nucleotide sequence is generally substituted for the nucleotide sequence of the poliovirus nucleic acid encoding at least a portion of a protein necessary for encapsidation. The invention further pertains to encapsidated recombinant poliovirus nucleic acids produced by the method of this invention and compositions containing the encapsidated or nonencapsidated recombinant poliovirus nucleic acid containing a foreign nucleotide sequence for use in a method of stimulating an immune response in a subject to the protein encoded by the foreign nucleotide sequence.</p>

ENCAPSIDATED RECOMBINANT POLIOVIRUS NUCLEIC ACID

Government Support

5 The work described herein was supported by Public Health Service contract (Mucosal Immunology Group) AI 15128, Public Health Service grant AI25005 from the National Institutes of Health, and National Cooperative Vaccine Development Grant (NCVDG) 2 UOI AI28147-06.

10 Background of the Invention

 The present invention relates to methods of encapsidating a recombinant viral nucleic acid having a foreign nucleotide sequence substituted for the nucleotide sequence of the virus encoding at least a portion of a protein necessary for encapsidation. More particularly, the invention relates to methods and compositions for generating an immune response in a
15 subject by using such a recombinant virus.

 Live or attenuated viruses have long been used to stimulate the immune system in a subject. Poliovirus is an attractive candidate system for delivery of antigens to the mucosal immune system because of several biological features inherent to the virus. First, the pathogenesis of the poliovirus is well-studied and the important features identified. The
20 poliovirus is naturally transmitted by an oral-fecal route and is stable in the harsh conditions of the intestinal tract. Primary replication occurs in the oropharynx and gastro-intestinal tract, with subsequent spread to the lymph nodes. Horstmann, D.M. et al. (1959) *JAMA* 170:1-8. Second, the attenuated strains of poliovirus are safe for humans, and are routinely administered to the general population in the form of the Sabin oral vaccine. The
25 incorporation of foreign genes into the attenuated strains would be an attractive feature that should pose no more of a health risk than that associated with administration of the attenuated vaccines alone. Third, the entire poliovirus has been cloned, the nucleic acid sequence determined, and the viral proteins identified. An infectious cDNA is also available for poliovirus which has allowed further genetic manipulation of the virus. Further, previous
30 studies using the attenuated vaccine strains of poliovirus have demonstrated that a long-lasting systemic and mucosal immunity is generated after administration of the vaccine. Sanders, D.Y. and Cramblett, H.G. (1974) *J. Ped.* 84:406-408; Melnick, J. (1978) *Bull. World Health Organ.* 56:21-38; Racaniello, V.R. and Baltimore, D. (1981) *Science* 214:916-919; Ogra, P.L. (1984) *Rev. Infect. Dis.* 6:S361-S368.

35 Recent epidemiological data suggest that worldwide more than seventy percent of infections with human immunodeficiency virus (HIV) are acquired by heterosexual intercourse through mucosal surfaces of the genital tract and rectum. Most HIV vaccines developed to date have been designed to preferentially stimulate the systemic humoral immune system and have relied on immunization with purified, whole human

immunodeficiency virus type 1 (HIV-1) and HIV-1 proteins (Haynes, B.F. (May 1993) *Science* 260:1279-1286.), or infection with a recombinant virus or microbe which expresses HIV-1 proteins (McGhee, J.R., and Mestecky, J. (1992) *AIDS Res. Rev.* 2:289-312). A general concern with these studies is that the method of presentation of the HIV-1 antigen to the immune system will not stimulate systemic and mucosal tissues to generate effective immunity at mucosal surfaces. Given the fact that the virus most often encounters a mucosal surface during sexual (vaginal or anal) transmission, a vaccine designed to stimulate both the systemic and mucosal immune systems is essential. McGhee, J.R., and Mestecky, J. (1992) *AIDS Res. Rev.* 2:289-312; Forrest, B.D. (1992) *AIDS Research and Human Retroviruses* 8:1523-1525.

In 1991, a group of researchers reported the construction and characterization of chimeric HIV-1-poliovirus genomes. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883. Segments of the HIV-1 proviral DNA containing the *gag*, *pol*, and *env* gene were inserted into the poliovirus cDNA so that the translational reading frame was conserved between the HIV-1 and poliovirus genes. The RNAs derived from the *in vitro* transcription of the genomes, when transfected into cells, replicated and expressed the appropriate HIV-1 protein as a fusion with the poliovirus P1 protein. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883. However, since the chimeric HIV-1-poliovirus genomes were constructed by replacing poliovirus capsid genes with the HIV-1 *gag*, *pol*, or *env* genes, the chimeric HIV-1-genomes were not capable of encapsidation after introduction into host cells. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883. Furthermore, attempts to encapsidate the chimeric genome by cotransfection with the poliovirus infectious RNA yielded no evidence of encapsidation. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883.

In 1992, another group of researchers reported the encapsidation of a poliovirus replicon which incorporated the reporter gene, chloramphenicol acetyltransferase (CAT), in place of the region coding for capsid proteins VP4, VP2, and a portion of VP3 in the genome of poliovirus type 3. Percy, N. et al. (Aug. 1992) *J. Virol.* 66(8):5040-5046. Encapsidation of the poliovirus replicon was accomplished by first transfecting host cells with the poliovirus replicon and then infecting the host cells with type 3 poliovirus. Percy, N. et al. (Aug. 1992) *J. Virol.* 66(8):5040, 5044. The formation of the capsid around the poliovirus genome is believed to be the result of interactions between capsid proteins and the poliovirus genome. Therefore, it is likely that the yield of encapsidated viruses obtained by Percy et al. consisted of a mixture of encapsidated poliovirus replicons and encapsidated nucleic acid from the type 3 poliovirus. The encapsidated type 3 poliovirus most likely represents a greater proportion of the encapsidated viruses than does the encapsidated poliovirus replicons. The Percy et al. method of encapsidating a poliovirus replicon is, therefore, an inefficient system for producing encapsidated recombinant poliovirus nucleic acid.

Accordingly, it would be desirable to provide a method of encapsidating a recombinant poliovirus genome which results in a stock of encapsidated viruses substantially

composed of the recombinant poliovirus genome. Such a method would enable the efficient production of encapsidated poliovirus nucleic acid for use in compositions for stimulating an immune response to foreign proteins encoded by the recombinant poliovirus genome.

5 Summary of the Invention

The present invention pertains to methods of encapsidating a recombinant poliovirus nucleic acid to obtain a yield of encapsidated viruses which substantially comprises encapsidated recombinant poliovirus nucleic acid. The methods of encapsidating a recombinant poliovirus nucleic acid include providing a recombinant poliovirus nucleic acid
10 which lacks the nucleotide sequence encoding at least a portion of a protein necessary for encapsidation and an expression vector lacking an infectious poliovirus genome, the nucleic acid of which encodes at least a portion of one protein necessary for encapsidation; contacting a host cell with the recombinant poliovirus nucleic acid and the expression vector under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the expression vector into the host cell; and obtaining a yield of encapsidated viruses which
15 substantially comprises an encapsidated recombinant poliovirus nucleic acid. The nucleic acid of the expression vector does not interact with the capsid proteins or portions of capsid proteins which it encodes, thereby allowing encapsidation of the recombinant poliovirus nucleic acid and avoiding encapsidation of the nucleic acid of the expression vector. The invention further pertains to encapsidated recombinant poliovirus nucleic acids produced by the methods of this invention.

In a preferred embodiment, the methods of encapsidating a recombinant poliovirus nucleic acid include providing a recombinant poliovirus nucleic acid in which the VP2 and VP3 genes of the P1 capsid precursor region of the poliovirus genome are replaced by a
25 foreign nucleotide sequence encoding, in an expressible form, a protein or fragment thereof, such as an immunogenic protein or fragment thereof. Examples of immunogenic proteins which can be encoded by the foreign nucleotide sequence include human immunodeficiency virus type 1 proteins and tumor-associated antigens. A host cell, e.g., a mammalian host cell, is then contacted with this recombinant poliovirus nucleic acid and an expression vector
30 lacking an infectious poliovirus genome, such as a vaccinia virus, which encodes the poliovirus P1 capsid precursor protein. Because the expression vector nucleic acid, e.g., vaccinia viral nucleic acid, does not compete with the recombinant poliovirus nucleic acid for the poliovirus capsid proteins, a yield of encapsidated viruses which substantially comprises encapsidated poliovirus nucleic acid is obtained. Further, the
35 resulting encapsidated recombinant poliovirus nucleic acid is able to direct expression of the foreign protein or fragment thereof.

In another preferred embodiment, the methods of encapsidating a recombinant poliovirus nucleic acid include providing a recombinant poliovirus nucleic acid in which the entire P1 capsid precursor region of the poliovirus genome is replaced by a foreign nucleotide

sequence encoding, in an expressible form, a protein or fragment thereof, such as an immunogenic protein or fragment thereof. A host cell, e.g., a mammalian host cell, is then contacted with this recombinant poliovirus nucleic acid and an expression vector lacking an infectious poliovirus genome, such as a vaccinia virus, which encodes the poliovirus P1 capsid precursor protein to thereby generate a yield of encapsidated viruses which substantially comprises encapsidated recombinant poliovirus nucleic acid. By these methods of encapsidating recombinant poliovirus nucleic acids, the upper size limit of the foreign nucleotide which can be inserted into the poliovirus nucleic acid is increased, thereby allowing expression of entire proteins, as well as fragments or portions of proteins. The present invention also pertains to encapsidated recombinant poliovirus nucleic acids which lack the entire P1 capsid precursor region.

The present invention further pertains to compositions for stimulating an immune response to an immunogenic protein or fragment thereof and a method for stimulating the immune response by administering the compositions to a subject. The compositions typically contain an encapsidated recombinant poliovirus nucleic acid, in a physiologically acceptable carrier, which encodes an immunogenic protein or fragment thereof and directs expression of the immunogenic protein, or fragment thereof. The compositions are administered to a subject in an amount effective to stimulate an immune response to the immunogenic protein or fragment thereof, e.g., in an amount effective to stimulate the production of antibodies against the immunogenic protein or fragment thereof in the subject.

The invention still further pertains to methods for generating cells that produce a foreign protein or fragment thereof. These methods include contacting host cells with an encapsidated recombinant poliovirus nucleic acid having a foreign nucleotide sequence substituted for the nucleotide sequence which encodes at least a portion of a protein necessary for encapsidating the recombinant poliovirus nucleic acid and an expression vector lacking an infectious poliovirus genome but which encodes and directs expression of at least a portion of a protein necessary for encapsidation of the recombinant poliovirus nucleic acid and directs expression of at least a portion of a protein necessary for encapsidating the recombinant poliovirus nucleic acid and maintaining the cultured host cells under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the expression vector into the host cells, thereby generating modified cells which produce a foreign protein or fragment thereof. Such modified cells can be reintroduced into the subject from which they were obtained to stimulate an immune response in the subject to the foreign protein or fragment thereof produced by the cells.

Brief Description of the Drawings

Figure 1 shows a schematic of the translation and proteolytic processing of the poliovirus polyprotein.

Figures 2A, 2B, and 2C show chimeric HIV-1-poliovirus genomes containing regions of the HIV-1 *gag* or *pol* gene substituted for the poliovirus P1 gene.

Figure 3 shows an SDS-polyacrylamide gel on which 3D^{pol} and HIV-1-P1 fusion protein expression from cells infected with VV-P1 and transfected with recombinant poliovirus RNA was analyzed.

Figures 4A, 4B, and 4C show SDS-polyacrylamide gels on which poliovirus- and HIV-1-specific protein expression from cells infected with recombinant poliovirus RNA which were encapsidated and serially passaged with capsid proteins provided by VV-P1 were analyzed.

Figure 5 shows a Northern blot analysis of RNA isolated from a stock of encapsidated recombinant poliovirus nucleic acid.

Figure 6 shows an SDS-polyacrylamide gel on which the neutralization of the poliovirus nucleic acid encapsidated by VV-P1 with anti-poliovirus antibodies was analyzed.

Figures 7A, 7B, and 7C show SDS-polyacrylamide gels on which poliovirus- and HIV-1-specific protein expression from cells infected with a stock of poliovirus nucleic acid encapsidated by type 1 Sabin poliovirus was analyzed.

Figures 8A, 8B, and 8C show total anti-poliovirus IgG levels in serum from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 9A, 9B, and 9C show anti-poliovirus IgA levels in saliva from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 10A and 10B show anti-poliovirus IgA in vaginal lavages after intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 11A, 11B, and 11C show anti-poliovirus IgA in feces from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 12A, 12B, and 12C show anti-HIV-1-Gag IgG in serum from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 13A, 13B, and 13C show anti-HIV-1-Gag IgA in saliva from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant

poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 14A and 14B show anti-HIV-1-Gag IgA in vaginal lavages from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 15A, 15B, and 15C show anti-HIV-1-Gag IgA in feces from mice after intragastric, intrarectal, and intramuscular administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figure 16 shows anti-poliovirus IgG from serum of a pigtail macaque after intrarectal administration of an encapsidated recombinant poliovirus nucleic acid encoding and expressing at least a portion of the *gag* protein of human immunodeficiency virus type 1.

Figures 17A, 17B, and 17C show recombinant poliovirus nucleic acids which contain the complete *gag* gene of HIV-1.

Figures 18A and 18B show an analysis of protein expression from cells transfected with RNA derived from recombinant poliovirus nucleic acid containing the *gag* gene of HIV-1.

Figures 19A and 19B show quantitation of recombinant poliovirus RNA from transfected cells by Northern blot.

Figure 20 shows an analysis of poliovirus and HIV-1 specific protein expression from cells infected with recombinant poliovirus nucleic acid encapsidated *in trans* using VV-P1.

Figures 21A and 21B show an analysis of protein expression from cells infected with normalized amounts of encapsidated recombinant poliovirus nucleic acid stocks and material derived from serial passage of equivalent amounts of encapsidated recombinant poliovirus nucleic acid virus stocks with VV-P1.

Figure 22 shows an analysis of protein expression from cells infected with material derived from the serial passage of encapsidated recombinant poliovirus nucleic acid with wild-type poliovirus.

Figures 23A, 23B, and 23C show construction of recombinant poliovirus nucleic acid containing the gene for carcinoembryonic antigen.

Figures 24A and 24B show expression, in transfected cells, of carcinoembryonic protein encoded by recombinant poliovirus nucleic acid containing the gene for carcinoembryonic antigen.

Figures 25A, 25B, and 25C show an analysis of poliovirus and carcinoembryonic expression from cells infected with recombinant poliovirus nucleic acid containing the gene for carcinoembryonic antigen: the recombinant poliovirus nucleic acid was encapsidated and serially passaged with capsid proteins provided by VV-P1.

Figures 26A and 26B show antibody response to encapsidated recombinant poliovirus nucleic acid expressing carcinoembryonic antigen.

Detailed Description of the Invention

5 The genome of poliovirus has been cloned and the nucleic acid sequence determined. The genomic RNA molecule is 7433 nucleotides long, polyadenylated at the 3' end and has a small covalently attached viral protein (VPg) at the 5' terminus. Kitamura, N. et al. (1981) *Nature* (London) 291:547-553; Racaniello, V.R. and Baltimore, D. (1981) *Proc. Natl. Acad. Sci. USA* 78:4887-4891. Expression of the poliovirus genome occurs via the translation of a
10 single protein (polyprotein) which is subsequently processed by virus encoded proteases (2A and 3C) to give the mature structural (capsid) and nonstructural proteins. Kitamura, N. et al. (1981) *Nature* (London) 291:547-553; Koch, F. and Koch, G. (1985) *The Molecular Biology of Poliovirus* (Springer-Verlag, Vienna). Poliovirus replication is catalyzed by the virus-encoded RNA-dependent RNA polymerase (3D^{pol}), which copies the genomic RNA to
15 give a complementary RNA molecule, which then serves as a template for further RNA production. Koch, F. and Koch, G. (1985) *The Molecular Biology of the Poliovirus* (Springer-Verlag, Vienna); Kuhn, R.J. and Wimmer, E. (1987) in D.J. Rowlands et al. (ed.) *Molecular Biology of Positive Strand RNA viruses* (Academic Press, Ltd., London).

20 The translation and proteolytic processing of the poliovirus polyprotein is depicted in Figure 1 which is a figure from Nicklin, M.J.H. et al. (1986) *Bio/Technology* 4:33-42. With reference to the schematic in Figure 1, the coding region and translation product of poliovirus RNA is divided into three primary regions (P1, P2, and P3), indicated at the top of the figure. The RNA is represented by a solid line and relevant nucleotide numbers are indicated by arrows. Protein products are indicated by waved lines. Cleavage sites are mapped onto the
25 polyprotein (top waved line) as filled symbols; open symbols represent the corresponding sites which are not cleaved. (∇, ∇) are QG pairs, (0,0) are YG pairs, and (◊, ◊) are NS pairs. Cleaved sites are numbered according to the occurrence of that amino-acid pair in the translated sequence. Where the amino acid sequence of a terminus of a polypeptide has been determined directly, an open circle has been added to the relevant terminus.

30 The mature poliovirus proteins arise by a proteolytic cascade which occurs predominantly at Q-G amino acid pairs. Kitamura, N. et al. (1981) *Nature* (London) 291:547-553; Semler, B.L. et al. (1981) *Proc. Natl. Acad. Sci. USA* 78:3763-3468; Semler, B.L. et al. (1981) *Virology* 114:589-594; Palmenberg, A.C. (1990) *Ann. Rev. Microbiol.* 44:603-623. A poliovirus-specific protein, 3C^{pro}, is the protease responsible for the majority
35 of the protease cleavages. Hanecak, R. et al. (1982) *Proc. Natl. Acad. Sci. USA*:79-3973-3977; Hanecak, R. et al. (1984) *Cell* 37:1063-1073; Nicklin, M.J.H. et al. (1986) *Bio/Technology* 4:33-42; Harris, K.L et al. (1990) *Seminars in Virol.* 1:323-333. A second viral protease, 2A^{pro}, autocatalytically cleaves from the viral polyprotein to release P1, the capsid precursor. Toyoda, H. et al. (1986) *Cell* 45:761-770. A second, minor cleavage by

- 2A^{pro} occurs within the 3D^{pol} to give 3C' and 3D'. Lee, Y.F. and Wimmer, E. (1988) *Virology* 166:404-414. Another role of the 2A^{pro} is the shut off of host cell protein synthesis by inducing the cleavage of a cellular protein required for cap-dependent translation. Bernstein, H.D. et al. (1985) *Mol. Cell Biol.* 5:2913-2923; Krausslich, H.G. et al. (1987) *J. Virol.* 61:2711-2718; Lloyd, R.E. et al. (1988) *J. Virol.* 62:4216-4223.

- Previous studies have established that the entire poliovirus genome is not required for RNA replication. Hagino-Yamagishi, K., and Nomoto, A. (1989) *J. Virol.* 63:5386-5392. Naturally occurring defective interfering particles (DIs) of poliovirus have the capacity for replication. Cole, C.N. (1975) *Prog. Med. Virol.* 20:180-207; Kuge, S. et al. (1986) *J. Mol. Biol.* 192:473-487. The common feature of the poliovirus DI genome is a partial deletion of the capsid (P1) region that still maintains the translational reading frame of the single polyprotein through which expression of the entire poliovirus genome occurs. In recent years, the availability of infectious cDNA clones of the poliovirus genome has facilitated further study to define the regions required for RNA replication. Racaniello, V. and Baltimore, D. (1981) *Science* 214:916-919. Specifically, the deletion of 1,782 nucleotides of P1, corresponding to nucleotides 1174 to 2956, resulted in an RNA which can replicate upon transfection into tissue culture cells. Hagino-Yamagishi, K. and Nomoto, A. (1989) *J. Virol.* 63:5386-5392.

- Early studies identified three poliovirus types based on reactivity to antibodies. Koch, F. and Koch, G. *The Molecular Biology of Poliovirus* (Springer-Verlag, Vienna 1985). These three serological types, designated as type I, type II, and type III, have been further distinguished as having numerous nucleotide differences in both the non-coding regions and the protein coding regions. All three strains are suitable for use in the present invention. In addition, there are also available attenuated versions of all three strains of poliovirus. These include the Sabin type I, Sabin type II, and Sabin type III attenuated strains of poliovirus that are routinely given to the population in the form of an oral vaccine. These strains can also be used in the present invention.

- The recombinant poliovirus nucleic acid of the present invention lacks the nucleotide sequence encoding at least a portion or a protein necessary for encapsidation of the recombinant poliovirus nucleic acid. The nucleotide sequence that is absent from the recombinant poliovirus nucleic acid can be any sequence at least a portion of which encodes at least a portion of a protein necessary for encapsidation, and the lack of which does not interfere with the ability of the poliovirus nucleic acid to replicate or to translate, in the correct reading frame, the single polyprotein through which expression of the entire poliovirus genome occurs. The recombinant poliovirus nucleic acid can be deoxyribonucleic acid (DNA) or ribonucleic acid (RNA). As the poliovirus genome is comprised of RNA which replicates in the absence of a DNA intermediate, it is typically introduced into a cell in the form of RNA. This avoids integration of the poliovirus genome into that of the host cell.

Proteins or portions of proteins necessary for encapsidation of a recombinant poliovirus nucleic acid include, for example, proteins or portions of proteins that are part of the capsid structure. Examples of such proteins are the proteins encoded by the VP1, VP2, VP3, and VP4 genes of the poliovirus P1 capsid precursor region, the Vpg protein, and those
5 proteins that are necessary for proper processing of structural proteins of the capsid structure, such as the proteases responsible for cleaving the viral polyprotein.

The nucleotide sequence lacking from the recombinant poliovirus nucleic acid can be the result of a deletion of poliovirus nucleotide sequences or a deletion of poliovirus nucleotide sequences and insertion of a foreign nucleotide sequence in the place of the
10 deleted sequences. Generally, the nucleotide sequence lacking from the recombinant poliovirus nucleic acid is the P1 region of the poliovirus genome or a portion thereof, which is replaced by a foreign gene. As used herein, the phrase "which lacks the entire P1 capsid precursor region" when used to refer to a recombinant poliovirus nucleic acid is intended to include recombinant poliovirus nucleic acids in which the nucleotide sequence encoding the
15 P1 capsid precursor protein has been deleted or altered such that the proteins which are normally encoded by this nucleotide sequence are not expressed or are expressed in a form which does not function normally. The proteins that are normally encoded by the P1 capsid precursor region of the poliovirus genome include the proteins encoded by the VP1, VP2, VP3, and VP4 genes. A recombinant poliovirus nucleic acid which lacks the entire P1
20 capsid precursor region, therefore, either does not include a nucleotide sequence which encodes the proteins encoded by the VP1, VP2, VP3, and VP4 genes or includes a nucleotide sequence which encodes, in unexpressible form or in expressible but not functional form, the proteins encoded by the VP1, VP2, VP3, and VP4 genes. In the present invention, it is specifically contemplated that recombinant poliovirus nucleic acids which lack the entire P1
25 capsid precursor region can include nucleotide sequences which encode amino acids which are included in the proteins encoded by the VP1, VP2, VP3, and VP4 genes so long as the nucleotide sequence encoding these amino acids of the capsid proteins do not encode the capsid proteins in expressible form or if in expressible form, not functional form. For example, in one embodiment of the invention, the entire P1 capsid precursor region of the
30 poliovirus genome, with the exception of a nucleotide sequence which encodes the first two amino acids (i.e., Met-Gly) of the poliovirus P1 capsid precursor protein, is deleted and replaced with a foreign nucleotide sequence. It is also specifically contemplated that additional nucleotide sequences from the poliovirus genome, e.g., nucleotide sequences which encode amino acid sequences which provide cleavage sites for poliovirus enzymes, e.g., 2A protease, or nucleotide sequences which encode other proteins required for proper
35 processing of a protein encoded by the poliovirus nucleic acid, can be included in recombinant poliovirus nucleic acids which lack the entire P1 capsid precursor region. Additional nucleotide sequences which encode amino acids which are used as spacers within the poliovirus polyprotein to provide an amino acid sequence of the proper length and of the

proper sequence for processing of the poliovirus polyprotein can also be included in recombinant poliovirus nucleic acids which lack the entire P1 capsid precursor region.

The foreign nucleotide sequence (or gene) which is substituted for a poliovirus nucleotide sequence preferably is one that encodes, in an expressible form, a foreign protein or fragment thereof. For example, foreign genes that can be inserted into the deleted region of the poliovirus nucleic acid can be those that encode immunogenic proteins. Such immunogenic proteins include, for example, tumor-associated antigens, e.g., human tumor-associated antigens, such as carcinoembryonic antigen (CEA), the ganglioside antigens GM2, GD2, and GD3 from melanoma cells, the antigen Jen CRG from colorectal and lung cancer cells, synthetic peptides of immunoglobulin epitope from B cell malignancies, antigens which are products of oncogenes such as *erb*, *neu*, and *sis*, or any other tumor-associated antigen, antigens obtained from various pathogens, such as hepatitis B surface antigen, influenza virus hemagglutinin and neuraminidase, human immunodeficiency viral proteins, such as *gag*, *pol*, and *env*, respiratory syncycial virus G protein, and the VP4 and VP1 proteins of rotavirus, bacterial antigens such as fragments of tetanus toxin, diphtheria toxin, and cholera toxin, mycobacterium tuberculosis protein antigen B, and urease protein from *Helicobacter pylori*. In addition, portions of the foreign genes which encode immunogenic proteins can be inserted into the deleted region of the poliovirus nucleic acid. These genes can encode linear polypeptides consisting of B and T cell epitopes. As these are the epitopes with which B and T cells interact, the polypeptides stimulate an immune response. It is also possible to insert chimeric foreign genes into the deleted region of the poliovirus nucleic acid which encode fusion proteins or peptides consisting of both B cell and T cell epitopes. Similarly, any foreign nucleotide sequence encoding an antigen from an infectious agent can be inserted into the deleted region of the poliovirus nucleic acid.

The foreign gene inserted into the deleted region of the poliovirus nucleic acid can also encode, in an expressible form, immunological response modifiers such as interleukins (e.g. interleukin-1, interleukin-2, interleukin-6, etc.), tumor necrosis factor (e.g. tumor necrosis factor- α , tumor necrosis factor- β), or additional cytokines (granulocyte-monocyte colony stimulating factor, interferon- γ). As an expression system for lymphokines or cytokines, the encapsidated poliovirus nucleic acid encoding the lymphokine or cytokine provides for limited expression (by the length of time it takes for the replication of the genome) and can be locally administered to reduce toxic side effects from systemic administration. In addition, genes encoding antisense nucleic acid, such as antisense RNA, or genes encoding ribozymes (RNA molecules with endonuclease or polymerase activities) can be inserted into the deleted region of the poliovirus nucleic acid. The antisense RNA or ribozymes can be used to modulate gene expression or act as anti-viral agents. Genes encoding herpes simplex thymidine kinase, which can be used for tumor therapy, SV40 T antigen, which can be used for cell immortalization, and protein products from herpes simplex virus, e.g., ICP-27, or adeno-associated virus, e.g., Rep, which can be used to

complement defective viral genomes can be inserted into the deleted region of the poliovirus nucleic acid.

Foreign genes encoding, in an expressible form, cell surface proteins, secretory proteins, or proteins necessary for proper cellular function which supplement a nonexistent, deficient, or nonfunctional cellular supply of the protein can also be inserted into the deleted region of the poliovirus nucleic acid. The nucleic acid of genes encoding secretory proteins comprises a structural gene encoding the desired protein in a form suitable for processing and secretion by the target cell. For example, the gene can be one that encodes appropriate signal sequences which provide for cellular secretion of the product. The signal sequence can be the natural sequence of the protein or exogenous sequences. In some cases, however, the signal sequence can interfere with the production of the desired protein. In such cases, the nucleotide sequence which encodes the signal sequence of the protein can be removed. See Example 7, below. The structural gene is linked to appropriate genetic regulatory elements required for expression of the gene product by the target cell. These include a promoter and optionally an enhancer element along with the regulatory elements necessary for expression of the gene and secretion of the gene encoded product.

In one embodiment, the foreign genes that are substituted for the capsid genes of the P1 capsid precursor region of the poliovirus genome are the *gag* (SEQ ID NO: 3; the sequence of the corresponding *gag* protein is represented by SEQ ID NO: 4), *pol* (SEQ ID NO: 5; the sequence of the corresponding *pol* protein is represented by SEQ ID NO: 6), or *env* (SEQ ID NO: 7; the sequence of the corresponding *env* protein is represented by SEQ ID NO: 8) genes, or portions thereof, of the human immunodeficiency virus type 1 (HIV-1). See Example 5, below. Portions of these genes are typically inserted in the poliovirus between nucleotides 1174 and 2956. The entire genes are typically inserted in the poliovirus between nucleotides 743 and 3359. The translational reading frame is thus conserved between the HIV-1 genes and the poliovirus genes. The chimeric HIV-1-poliovirus RNA genomes replicate and express the appropriate HIV-1-P1 fusion proteins upon transfection into tissue culture. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883. In another embodiment, foreign genes encoding tumor-associated antigens or portions thereof, such as carcinoembryonic antigen or portions thereof can be substituted for the capsid genes of the P1 capsid precursor region of the poliovirus genome. See Example 7, below.

Deletion or replacement of the P1 capsid region of the poliovirus genome or a portion thereof results in a poliovirus nucleic acid which is incapable of encapsidating itself. Choi, W.S. et al. (June 1991) *J. Virol.* 65(6):2875-2883. Typically, capsid proteins or portions thereof mediate viral entry into cells. Therefore, poliovirus nucleic acid which is not enclosed in a capsid enters cells on which there is a poliovirus receptor less efficiently than encapsidated poliovirus nucleic acid. It is preferred, but not required, therefore, that essential capsid proteins from another source be provided for encapsidation and delivery of the foreign genes to cells. In the method of this invention, essential poliovirus capsid proteins are

provided by an expression vector which is introduced into the host cell along with the recombinant poliovirus nucleic acid. The expression vectors can be introduced into the host cell prior to, concurrently with, or subsequent to the introduction of the recombinant poliovirus nucleic acid. In an alternative embodiment, nonencapsidated recombinant poliovirus nucleic acid can be delivered directly to target cells, e.g., by direct injection into, for example, muscle cells (see, for example, Acsadi et al. (1991) *Nature* 332: 815-818; Wolff et al. (1990) *Science* 247:1465-1468), or by electroporation, transfection mediated by calcium phosphate, transfection mediated by DEAE-dextran, liposome-mediated transfection (Nicolau et al. (1987) *Meth. Enz.* 149:157-176; Wang and Huang (1987) *Proc. Natl. Acad. Sci. USA* 84:7851-7855; Brigham et al. (1989) *Am. J. Med. Sci.* 298:278; and Gould-Fogerite et al. (1989) *Gene* 84:429-438), or receptor-mediated nucleic acid uptake (see for example Wu, G. and Wu, C.H. (1988) *J. Biol. Chem.* 263:14621; Wilson et al. (1992) *J. Biol. Chem.* 267:963-967; and U.S. Patent No. 5,166,320), or other methods of delivering naked nucleic acids to target cells, both *in vivo* and *in vitro*, known to those of ordinary skill in the art.

In a preferred method of encapsidating the recombinant poliovirus nucleic acid, the expression vector is introduced into the host cell prior to the introduction of the recombinant poliovirus nucleic acid. The introduction of the expression vector into the host cell prior to the introduction of the recombinant poliovirus nucleic acid allows the initial expression of the protein or portion of the protein necessary for encapsidation by the expression vector.

Previous studies have established that the replication and expression of the poliovirus genes in cells results in the shutoff of host cell protein synthesis which is accomplished by the 2A^{pro} protein of poliovirus. Thus, in order for efficient encapsidation, the expression vector must express the protein necessary for encapsidation. In order for this to occur, the expression vector is generally introduced into the cell prior to the addition of the recombinant poliovirus nucleic acid.

Expression vectors suitable for use in the present invention include plasmids and viruses, the nucleic acids of which encode at least a portion of a protein necessary for encapsidation of the recombinant poliovirus nucleic acid and direct expression of the nucleotide sequence encoding at least a portion of a protein necessary for encapsidation of the recombinant poliovirus nucleic acid. In addition, the nucleic acid of the expression vectors of the present invention does not substantially associate with poliovirus capsid proteins or portions thereof. Therefore, expression vectors of the present invention, when introduced into a host cell along with the recombinant poliovirus nucleic acid, result in a host cell yield of encapsidated viruses which is substantially composed of encapsidated recombinant poliovirus nucleic acid. As used herein, the phrases "substantially composed" or "substantially comprises" when used to refer to a yield of encapsidated recombinant poliovirus nucleic acids is intended to include a yield of encapsidated recombinant poliovirus nucleic acid which is greater than a yield of encapsidated recombinant poliovirus nucleic acid which is generated through the use of an expression vector which encodes poliovirus capsid

proteins but also includes an infectious poliovirus genome. Infectious poliovirus genomes can compete with the recombinant poliovirus nucleic acid for poliovirus capsid proteins, thereby decreasing the yield of encapsidated recombinant poliovirus nucleic acid. Generally, the nucleic acid of the expression vector encodes and directs expression of the nucleotide
5 sequence coding for a capsid protein which the recombinant poliovirus nucleic acid is not capable of expressing. For example, the expression vector can encode the entire P1 capsid precursor protein.

Plasmid expression vectors can typically be designed and constructed such that they contain a gene encoding, in an expressible form, a protein or a portion of a protein necessary
10 for encapsidation of the recombinant poliovirus nucleic acid. Generally, construction of such plasmids can be performed using standard methods, such as those described in Sambrook, J. et al. Molecular Cloning: A Laboratory Manual, 2nd edition (CSHL Press, Cold Spring Harbor, NY 1989). A plasmid expression vector which expresses a protein or a portion of a protein necessary for encapsidation of the poliovirus nucleic acid is constructed by first
15 positioning the gene to be inserted (e.g. VP1, VP2, VP3, VP4 or the entire P1 region) after a DNA sequence known to act as a promoter when introduced into cells. The gene to be inserted is typically positioned downstream (3') from the promoter sequence. The promoter sequence consists of a cellular or viral DNA sequence which has been previously demonstrated to attract the necessary host cell components required for initiation of
20 transcription. Examples of such promoter sequences include the long terminal repeat (LTR) regions of Rous Sarcoma Virus, the origin of replication for the SV40 tumor virus (SV40-ori), and the promoter sequence for the CMV (cytomegalovirus) immediate early protein. Plasmids containing these promoter sequences are available from a number of companies which sell molecular biology products (e.g. Promega (Madison, WI), Stratagene Cloning
25 Systems (LaJolla, CA), and Clontech (Palo Alto, CA).

Construction of these plasmid expression vectors typically requires excision of a DNA fragment containing the gene to be inserted and ligation of this DNA fragment into an expression plasmid cut with restriction enzymes that are compatible with those contained on the 5' and 3' ends of the gene to be inserted. Following ligation of the DNA *in vitro*, the
30 plasmid is transformed into *E. coli* and the resulting bacteria is plated onto an agar plate containing an appropriate selective antibiotic. The *E. coli* colonies are then grown and the plasmid DNA characterized for the insertion of the particular gene. To confirm that the gene has been ligated into the plasmid, the DNA sequence of the plasmid containing the insert is determined. The plasmid expression vector can be transfected into tissue culture cells using
35 standard techniques and the protein encoded by the inserted gene expressed.

The conditions under which plasmid expression vectors are introduced into a host cell vary depending on certain factors. These factors include, for example, the size of the nucleic acid of the plasmid, the type of host cell, and the desired efficiency of transfection. There are several methods of introducing the recombinant poliovirus nucleic acid into the host cells

which are well-known and commonly employed by those of ordinary skill in the art. These transfection methods include, for example, calcium phosphate-mediated uptake of nucleic acids by a host cell and DEAE-dextran facilitated uptake of nucleic acid by a host cell.

Alternatively, nucleic acids can be introduced into cells through electroporation, (Neumann, E. et al. (1982) *EMBO J.* 1:841-845), which is the transport of nucleic acids directly across a cell membrane by means of an electric current or through the use of cationic liposomes (e.g. lipofection, Gibco/BRL (Gaithersburg, MD)). The methods that are most efficient in each case are typically determined empirically upon consideration of the above factors.

As with plasmid expression vectors, viral expression vectors can be designed and constructed such that they contain a foreign gene encoding a foreign protein or fragment thereof and the regulatory elements necessary for expressing the foreign protein. Viruses suitable for use in the method of this invention include viruses that contain nucleic acid that does not substantially associate with poliovirus capsid proteins. Examples of such viruses include retroviruses, adenoviruses, herpes virus, and Sindbis virus. Retroviruses, upon introduction into a host cell, establish a continuous cell line expressing a foreign protein. Adenoviruses are large DNA viruses which have a host range in human cells similar to that of poliovirus. Sindbis virus is an RNA virus that replicates, like poliovirus, in the cytoplasm of cells and, therefore, offers a convenient system for expressing poliovirus capsid proteins. A preferred viral expression vector is a vaccinia virus. Vaccinia virus is a DNA virus which replicates in the cell cytoplasm and has a similar host range to that of poliovirus. In addition, vaccinia virus can accommodate large amounts of foreign DNA and can replicate efficiently in the same cell in which poliovirus replicates. A preferred nucleotide sequence that is inserted in the vaccinia is the nucleotide sequence encoding and expressing, upon infection of a host cell, the poliovirus P1 capsid precursor polypeptide.

The construction of this vaccinia viral vector is described by Ansardi, D.C. et al. (Apr. 1991) *J. Virol.* 65(4):2088-2092. Briefly, type I Mahoney poliovirus cDNA sequences were digested with restriction enzyme NdeI, releasing sequences corresponding to poliovirus nucleotides 3382-6427 from the plasmid and deleting the P2 and much of the P3 encoding regions. Two synthetic oligonucleotides, (5'-TAT-TAG-TAG-ATC-TG (SEQ ID NO: 1)) and 5'-T-ACA-GAT-GTA-CTA-A (SEQ ID NO: 2)) were annealed together and ligated into the NdeI digested DNA. The inserted synthetic sequence is places two translational termination codons (TAG) immediately downstream from the codon for the synthetic P1 carboxy terminal tyrosine residue. Thus, the engineered poliovirus sequences encode an authentic P1 protein with a carboxy terminus identical to that generated when 2A^{pro} releases the P1 polypeptide from the nascent poliovirus polypeptide. An additional modification was also generated by the positioning of a SalI restriction enzyme site at nucleotide 629 of the poliovirus genome. This was accomplished by restriction enzyme digest (Ball) followed by ligation of synthetic SalI linkers. The DNA fragment containing the poliovirus P1 gene was subcloned into the vaccinia virus recombination plasmid, pSC11. Chackrabarti, S. et al.

(1985) *Mol. Cell Biol.* 5:3403-3409. Coexpression of beta-galactosidase provides for visual screening of recombinant virus plaques.

The entry of viral expression vectors into host cells generally requires addition of the virus to the host cell media followed by an incubation period during which the virus enters
5 the cell. Incubation conditions, such as the length of incubation and the temperature under which the incubation is carried out, vary depending on the type of host cell and the type of viral expression vector used. Determination of these parameters is well known to those having ordinary skill in the art. In most cases, the incubation conditions for the infection of cells with viruses typically involves the incubation of the virus in serum-free medium
10 (minimal volume) with the tissue culture cells at 37°C for a minimum of thirty minutes. For some viruses, such as retroviruses, a compound to facilitate the interaction of the virus with the host cell is added. Examples of such infection facilitators include polybrine and DEAE.

A host cell useful in the present invention is one into which both a recombinant poliovirus nucleic acid and an expression vector can be introduced. Common host cells are
15 mammalian host cells, such as, for example, HeLa cells (ATCC Accession No. CCL₂ 2), HeLa S3 (ATCC Accession No. CCL 2.2), the African Green Monkey cells designated BSC-40 cells, which are derived from BSC-1 cells (ATCC Accession No. CCL 26), and HEp-2 cells (ATCC Accession No. CCL 23). Other useful host cells include chicken cells. Because the recombinant poliovirus nucleic acid is encapsidated prior to serial passage, host cells for such
20 serial passage are preferably permissive for poliovirus replication. Cells that are permissive for poliovirus replication are cells that become infected with the recombinant poliovirus nucleic acid, allow viral nucleic acid replication, expression of viral proteins, and formation of progeny virus particles. *In vitro*, poliovirus causes the host cell to lyse. However, *in vivo* the poliovirus may not act in a lytic fashion. Nonpermissive cells can be adapted to become
25 permissive cells, and such cells are intended to be included in the category of host cells which can be used in this invention. For example, the mouse cell line L929, a cell line normally nonpermissive for poliovirus replication, has been adapted to be permissive for poliovirus replication by transfection with the gene encoding the poliovirus receptor. Mendelsohn, C.L. et al. (1989) *Cell* 56:855-865; Mendelsohn, C.L. et al. (1986) *Proc. Natl. Acad. Sci. USA*
30 83:7845-7849.

The encapsidated recombinant poliovirus nucleic acid of the invention can be used as a vaccine in the form of a composition for stimulating a mucosal as well as a systemic immune response to the foreign protein encoded and expressed by the encapsidated recombinant poliovirus nucleic acid in a subject. Examples of genes encoding proteins that
35 can be inserted into the poliovirus nucleic acid are described above. The mucosal immune response is an important immune response because it offers a first line of defense against infectious agents, such as human immunodeficiency virus, which can enter host cells via mucosal cells. At least a portion of a capsid protein of the encapsidated recombinant poliovirus nucleic acid is supplied by an expression vector which lacks an infectious

poliovirus genome. Expression vectors suitable for supplying a capsid protein or a portion thereof are described above. Upon administration of the encapsidated recombinant poliovirus nucleic acid, the subject generally responds to the immunizations by producing both anti-poliovirus antibodies and antibodies to the foreign protein or fragment thereof which is expressed by the recombinant poliovirus nucleic acid. The antibodies produced against the foreign protein or fragment thereof provide protection against the disease or detrimental condition caused by the source of the protein or fragment thereof, e.g., virus, bacteria, or tumor cell. The protection against disease or detrimental conditions offered by these antibodies is greater than the protection offered by the subject's immune system absent administration of the recombinant poliovirus nucleic acids of the invention. The recombinant poliovirus nucleic acid, in either its DNA or RNA form, can also be used in a composition for stimulating a systemic and a mucosal immune response in a subject. Administration of the RNA form of the recombinant poliovirus nucleic acid is preferred as it typically does not integrate into the host cell genome.

The encapsidated recombinant poliovirus nucleic acid or the non-encapsidated recombinant poliovirus nucleic acid can be administered to a subject in a physiologically acceptable carrier and in an amount effective to stimulate an immune response to at least the foreign protein or fragment thereof which is encoded (and its expression directed) by the recombinant poliovirus nucleic acid. Typically, a subject is immunized through an initial series of injections (or administration through one of the other routes described below) and subsequently given boosters to increase the protection afforded by the original series of administrations. The initial series of injections and the subsequent boosters are administered in such doses and over such a period of time as is necessary to stimulate an immune response in a subject.

Physiologically acceptable carriers suitable for injectable use include sterile aqueous solutions (where water soluble) or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. The composition should typically be sterile and fluid to the extent that easy syringability exists. The composition should further be stable under the conditions of manufacture and storage and should be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), suitable mixtures thereof, and vegetable oils. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prevention of the action of microorganisms can be achieved by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, ascorbic acid, thimerosal, and the like.

Sterile injectable solutions can be prepared by incorporating the encapsidated recombinant poliovirus nucleic acid in the required amount in an appropriate solvent with

one or a combination of ingredients enumerated above, as required, followed by filtered sterilization.

When the encapsidated or nonencapsidated recombinant poliovirus nucleic acid is suitably protected, as described above, the protein can be orally administered, for example, with an inert diluent or an assimilable edible carrier. The protein and other ingredients can also be enclosed in a hard or soft shell gelatin capsule, compressed into tablets, or incorporated directly into the individual's diet. For oral therapeutic administration, the active compound can be incorporated with excipients and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups, wafers, and the like.

As used herein "physiologically acceptable carrier" includes any and all solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents, and the like. The use of such media and agents for physiologically active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the active compound, use thereof in the therapeutic compositions is contemplated.

Subjects who can be treated by the method of this invention include living organisms, e.g., mammals. Typically, subjects who can be treated by the method of this invention are susceptible to diseases, e.g., infectious diseases, cancer, or are susceptible to a detrimental condition which can be treated by the methods described herein, e.g., a detrimental condition resulting from a nonexistent, deficient, or nonfunctional supply of a protein which is normally produced in the subject. Infectious agents which initiate a variety of diseases include microorganisms such as viruses and bacteria. Examples of subjects include humans, monkeys, dogs, cats, rats, and mice.

The amount of the immunogenic composition which can stimulate an immune response in a subject can be determined on an individual basis and is typically based, at least in part, on consideration of the activity of the specific immunogenic composition used. Further, the effective amounts of the immunogenic composition can vary according to the age, sex, and weight of the subject being treated. Thus, an effective amount of the immunogenic composition can be determined by one of ordinary skill in the art employing such factors as described above using no more than routine experimentation.

The immunogenic composition is administered through a route which allows the composition to perform its intended function of stimulating an immune response to the protein encoded by the recombinant poliovirus nucleic acid. Examples of routes of administration which can be used in this method include parenteral (subcutaneous, intravenous, intramuscular, intra-arterial, intraperitoneal, intrathecal, intracardiac, and intrasternal), enteral administration (i.e. administration via the digestive tract, e.g. oral, intragastric, and intrarectal administration), and mucosal administration. It is important to note that the vaccine strains of poliovirus are routinely tested for attenuation by intramuscular and intracerebral injection into monkeys. Thus, it would probably pose no associated health

risk if the recombinant poliovirus nucleic acid was given parenterally. Depending on the route of administration, the immunogenic composition can be coated with or in a material to protect it from the natural conditions which can detrimentally affect its ability to perform its intended function.

5 Cells that produce the encapsidated poliovirus nucleic acids of the present invention can be introduced into a subject, thereby stimulating an immune response to the foreign protein or fragment thereof encoded by the recombinant poliovirus nucleic acid. Generally, the cells that are introduced into the subject are first removed from the subject and contacted
10 *ex vivo* with both the recombinant poliovirus nucleic acid and an expression vector as described above to generate modified cells that produce the foreign protein or fragment thereof. The modified cells that produce the foreign protein or fragment thereof can then be reintroduced into the subject by, for example, injection or implantation. Examples of cells that can be modified by this method and injected into a subject include peripheral blood mononuclear cells, such as B cells, T cells, monocytes and macrophages. Other cells, such as
15 cutaneous cells and mucosal cells can be modified and implanted into a subject. Methods of introducing the recombinant poliovirus nucleic acid and the expression vectors of the invention are described above.

 The invention is further illustrated by the following non-limiting examples. The contents of all references and issued patents cited throughout this application are expressly
20 incorporated herein by reference.

MATERIALS AND METHODS I:

 The following materials and methods were used in Examples 1, 2, 3, and 4:

 All chemicals were purchased from Sigma Chemical Co. (St. Louis, MO). Restriction
25 enzymes were obtained from New England Bio-labs (Beverly, MA). Tissue culture media was purchased from Gibco/BRL Co. (Gaithersburg, MD). ³⁵S Translabel (methionine-cysteine) and methionine-cysteine-free Dulbecco modified Eagle medium (DMEM) were purchased from ICN Biochemicals (Irvine, CA). T7 RNA polymerase was prepared in this laboratory by the method of Grodberg and Dunn. Grodberg, J. and Dunn, J.J. (1988) *J.*
30 *Bacteriol.* 170:1245-1253.

Tissue culture cells and viruses

 HeLa (human cervical carcinoma) and BSC-40 cells (African green monkey kidney cells) were grown in DMEM supplemented with 5% A-γ newborn calf serum and 5% fetal
35 calf serum (complete medium). The stock of the poliovirus type 1 Mahoney used in this study was derived from transfection of an infectious cDNA clone obtained from B. Semler, University of California at Irvine. Semler, B.L. et al. (1984) *Nucleic Acids Res.* 12:5123-5141. The stock of type 1 Sabin poliovirus was obtained from the American Type Culture Collection (ATCC Accession No. VR-192). Wild-type vaccinia virus (wt VV) strain WR and

- the recombinant vaccinia virus VV-P1, which express the poliovirus P1 capsid precursor protein, have been previously described. Ansardi, D.C. et al. (1991) *J. Virol.* 65:2088-2092. Antisera to HIV-1 reverse transcriptase (RT) and HIV-1 p25/24 Gag (Steimer, K.S. et al. (1986) *Virology* 150:283-290) were obtained through the AIDS Research and Reference
- 5 Reagent Program (Rockville, MD). Pooled AIDS patient sera was obtained from the Center for AIDS Research, University of Alabama at Birmingham.

In vitro transcription reaction

- The *in vitro* transcription reactions were performed by using T7 RNA polymerase as described previously. Choi, W.S. et al (1991) *J. Virol.* 65:2875-2883. Prior to *in vitro* transcription, DNA templates were linearized by restriction enzyme digestion, followed by successive phenol-chloroform (1:1) chloroform extractions and ethanol precipitation. Reaction mixtures (100 μ l) contained 1 to 5 μ g of linearized DNA template, 5x transcription buffer (100 mM Tris [pH 7.7], 50 mM MgCl₂, 20 mM spermidine, 250 mM NaCl), 10 mM
- 15 dithiotheritol, 2mM each GTP, UTP, ATP, and CTP, 40 U of recombinant RNasin (Promega, Madison, WI), and approximately 5 μ g of purified T7 RNA polymerase per reaction mixture. After 60 min at 37°C, 5% of the *in vitro*-synthesized RNA was analyzed by agarose gel electrophoresis.

Encapsidation and serial passage of recombinant poliovirus nucleic acids by VV-P1

- HeLa cells were infected with 20 PFU of VV-P1 (a recombinant virus which expresses the poliovirus capsid precursor protein P1) or wild type (wt) VV per cell. After 2 hours of infection, the cells were transfected (by using DEAE-dextran [500,000 Da] as a facilitator) with RNA transcribed *in vitro* from the chimeric HIV-1 poliovirus genomes as
- 25 previously described. Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883. The cultures were harvested at 24 hours posttransfection. The cells were lysed with Triton X-100 at a concentration of 1%, treated with RNase A, and clarified by low-speed centrifugation at 14,000 x g for 20 min at 4°C as described previously. Li, G. et al. (1991) *J. Virol.* 65:6714-6723. The supernatants were adjusted to 0.25% sodium dodecyl sulfate (SDS), overlaid on a
- 30 30% sucrose cushion (30% sucrose, 30 mM Tris [pH 8.0], 1% Triton X-100, 0.1 M NaCl), and centrifuged in a Beckman SW55Ti rotor at 45,000 rpm for 1.5h. The pelleting procedure described above has been demonstrated to be effective for the removal of infectious vaccinia virus to below detectable levels. The supernatant was discarded, and the pellet was washed by recentrifugation for an additional 1.5 hours in a low salt buffer (30mM Tris [pH 8.0], 0.1
- 35 M NaCl). The pellets were then resuspended in complete DMEM and designated passage 1 of the recombinant poliovirus nucleic acids encapsidated by VV-P1.

For serial passage of the encapsidated recombinant poliovirus nucleic acids, BSC-40 cells were infected with 20 PFU of VV-P1 per cell. At 2 hours postinfection, the cells were infected with passage 1 of the encapsidated recombinant poliovirus nucleic acids. The

cultures were harvested at 24 hours postinfection by three successive freeze-thaws, sonicated, and clarified by centrifugation at 14,000 x g for 20 min. The supernatants were then stored at -70°C or used immediately for additional passages following the same procedure.

5 Metabolic labeling and immunoprecipitation of viral proteins

To metabolically label viral proteins from infected-transfected or infected cells, the cultures were starved for methionine-cysteine at 6 hours postinfection by incubation in DMEM minus methionine-cysteine for 30 minutes. At the end of this time, ³⁵S Translabel was added for an additional hour. Cultures were then processed for immunoprecipitation of
10 viral proteins by lysing the cells with radioimmunoprecipitation assay (RIPA) buffer (150 mM NaCl, 10 mM Tris [pH 7.8], 1% Triton X-100, 1% sodium deoxycholate, 0.2% SDS). Following centrifugation at 14,000 x g for 10 min to pellet any debris, designated antibodies were added to the supernatants, which were incubated at 4°C rocking for 24 hours. The immunoprecipitates were collected by addition of 100 µl of protein A-Sepharose (10%
15 [wt/vol] in RIPA buffer). After 1 hour of rocking at room temperature, the protein A-Sepharose beads were collected by brief configuration and washed three times with RIPA buffer. The bound material was eluted by boiling for 5 minutes in gel sample buffer (50 mM Tris [pH 6.8], 5% SDS, 10% glycerol, 0.01% bromophenol blue, 10% β-mercaptoethanol). The proteins were analyzed by SDS polyacrylamide gel electrophoresis, and radiolabeled
20 proteins were visualized by fluorography.

Nucleic acid hybridization

RNA from a stock of recombinant poliovirus nucleic acids encapsidated by VV-P1 was analyzed by Northern (RNA) blotting. Stocks of encapsidated recombinant poliovirus
25 nucleic acids at passage 14 and a high-titer stock of type 1 Mahoney poliovirus were subjected to RNase A treatment and overlaid on 30% sucrose cushion (30% sucrose, 30mM Tris [pH 8.0], 1% Triton X-100, 0.1 M NaCl). The samples were centrifuged in a Beckman SW55Ti rotor at 45,000 rpm for 1.5h. Pelleted virions were resuspended in TSE buffer (10 mM Tris-HCl [pH 8.0], 50 mM EDTA) and adjusted to 1% SDS and 1% β-mercaptoethanol
30 as previously described. Rico-Hesse, R. et al. (1987) *Virology* 160:311-322. The resuspended virions were disrupted by extraction three times with phenol-chloroform equilibrated to acidic buffer and one time with chloroform. The extracted RNA was precipitated with 0.2 M LiCl₂, and 2.5 volumes 100% ethanol. The RNA was denatured and separated on a formaldehyde-agarose gel. The RNA was then transferred from the gel to a
35 nitrocellulose filter by capillary elution (Sambrook, J. et al. (1989) *Molecular Cloning: A Laboratory Manual*, 2nd edition (Cold Spring Harbor Laboratory Press, NY)) and cross-linked by using a UV Stratalinker (Stratagene, LaJolla, CA). The conditions used for prehybridization, hybridization, and washing of RNA immobilized on filters were previously described (Sambrook, J. et al. (1989) *Molecular Cloning: A Laboratory Manual*, 2nd edition

(Cold Spring Harbor Laboratory Press, NY)). Briefly, the blot was prehybridized in hybridization buffer (50% deionized formamide, 6x SSC [1x SSC is 0.15 M NaCl plus 0.015 M sodium citrate], 1% SDS, 0.1% Tween 20, 100µg of yeast tRNA per ml). The blot was then incubated in hybridization buffer containing 10^6 cpm of a [32 P] UTP-labeled riboprobe complementary to nucleotides 671 to 1174 of the poliovirus genome (Choi, W.S. et al (1991) *J. Virol.* 65:2875-2883) per ml. After hybridization, the blot was washed two times with 0.1 x SSC-0.1% SDS at room temperature and one time at 65°C. The blot was then exposed to X-ray film with an intensifying screen.

10 Neutralization of the recombinant poliovirus nucleic acids encapsidated by VV-P1 using anti-poliovirus antibodies

For antibody neutralization, encapsidated recombinant poliovirus nucleic acids at passage 9 were pelleted by ultracentrifugation and resuspended in 250 µl of phosphate-buffered saline (pH 7.0)-0.1% bovine serum albumin. Samples were preincubated with 25 µl of either rabbit anti-poliovirus type 1 Mahoney antisera or preimmune sera per sample at 37° C for 2 hours. Neutralization experiments were conducted on the basis of the results of preliminary experiments analyzing the capacity of anti-poliovirus antisera to prevent infection of cells by 10^6 total PFU of poliovirus under the experimental conditions. The preincubated samples were then analyzed for protein expression by infection of BSC-40 cells which were metabolically labeled at 6 hours postinfection followed by immunoprecipitation of viral proteins.

Encapsidation of the recombinant poliovirus nucleic acids by type 1 Sabin poliovirus

BSC-40 cells were coinfectd with 10 PFU of type 1 Sabin poliovirus and a stock of encapsidated recombinant poliovirus nucleic acids (passage 14) per cell. The infected cells were harvested at 24 hours postinfection by three successive freeze-thaws, sonicated and clarified by centrifugation at 14,000 x g for 20 minutes as described previously (Li, G.. et al. *J. Virol.* 65:6714-6723). Approximately one-half of the supernatant was used for serial passaging by reinfection of BSC-40 cells. After 24 hours, the cultures were harvested as described above, and the procedure was repeated for an additional 10 serial passages.

EXAMPLE 1: EXPRESSION OF RECOMBINANT POLIOVIRUS NUCLEIC ACID IN WHICH THE VP2 AND VP3 REGIONS OF THE POLIOVIRUS GENOME ARE REPLACED WITH A PORTION OF THE HIV-1 GAG OR POL GENES IN CELLS INFECTED WITH AN EXPRESSION VECTOR WHICH EXPRESSES THE POLIOVIRUS CAPSID PRECURSOR PROTEIN P1

The construction and characterization of recombinant poliovirus nucleic acid in which the HIV-1 *gag* or *pol* gene was substituted for VP2 and VP3 regions of the poliovirus P1 protein, in the infectious cDNA of poliovirus have previously been described. Choi, W.S. et al (1991) *J. Virol.* 65:2875-2883 (Figure 2). Figure 2 shows chimeric HIV-1-poliovirus genomes containing regions of the HIV-1 *gag* or *pol* gene substituted for the poliovirus P1 gene. Details of the construction of plasmids pT7-IC-GAG 1 and pT7-IC-POL have been described by Choi et al. and were presented as pT7IC-NheI-*gag* and pT7IC-NheI-*pol*, respectively. To construct pT7-IC-GAG 2, a unique *Sma*I site was created at nucleotide 1580 of the infectious cDNA or poliovirus, and the HIV-1 *gag* sequences were subcloned between nucleotides 1580 and 2470. Insertion of the HIV-1 genes maintains the translational reading frame with VP4 and VP1. *In vitro* transcription from these plasmids generates full-length RNA transcripts (linearized with *Sall*). Transfection of full-length transcripts into HeLa cells results in expression of the poliovirus 3CD protein, a fusion protein between the 3C^{Pro} and the 3D^{Pol} proteins with a molecular mass of 72 kDa. The molecular masses of the HIV-1-P1 fusion proteins are indicated. In previous studies, transfection of these chimeric RNA genomes into type 1 Mahoney poliovirus-infected cells did not result in encapsidation of these RNA genomes (Choi, W.S. et al (1991) *J. Virol.* 65:2875-2883). Under the experimental conditions used, it was possible that the recombinant poliovirus nucleic acid did not efficiently compete with wild-type RNA genomes for capsid proteins. To circumvent this problem, a recombinant vaccinia virus (VV-P1) which expresses the poliovirus capsid precursor protein P1 upon infection was used, since recent studies have shown that in cells coinfecting with VV-P1 and poliovirus, P1 protein expressed from VV-P1 can enter the encapsidation pathways of wild type poliovirus.

Protein expression from the recombinant poliovirus nucleic acid transfected into cells previously infected with the recombinant vaccinia virus VV-P1 was analyzed. (Figure 3) Figure 3 shows an analysis of 3D^{Pol} and HIV-1-P1 fusion protein expression from cells infected with VV-P1 and transfected with recombinant poliovirus nucleic acid RNAs. Cells were infected with VV-P1 at a multiplicity of infection of 20. At 2 hours postinfection, cells were transfected with RNA derived from *in vitro* transcription of the designated plasmids. Cells were metabolically labeled and cells extracts were incubated with anti-3D^{Pol} antibodies (lanes 1 to 5), pooled AIDS patient sera (lanes 6 to 8), or anti-RT antibodies (lane 9), and immunoreactive proteins were analyzed on SDS-polyacrylamide gels. Lanes: 1, cells

infected with wild-type poliovirus: 2 and 6, mock-transfected cells: 3 and 7, cells transfected with RNA derived from pT7-IC-GAG 1: 4 and 8, cells transfected with RNA derived from pT7-IC-GAG 2; 5 and 9, cells transfected with RNA derived from pT7-IC-POL. The positions of molecular mass standards are indicated. A protein of molecular mass 72 kDa, corresponding to the 3CD protein of poliovirus, was immunoprecipitated by anti-3D^{pol} antibodies from cells transfected with the recombinant poliovirus RNA but not from mock-transfected cells. Under the same conditions for metabolic labeling, the 3CD protein, which is a fusion protein between the 3C^{pol} and 3D^{pol} proteins of poliovirus, is predominately detected upon incubation of lysates from poliovirus infected cells with 3D^{pol} antisera to determine whether the appropriate HIV-1-P1 fusion proteins were also expressed, the extracts were incubated with pooled AIDS patient sera (*gag*) or rabbit anti-RT antibodies (*pol*). Expression of the HIV-1-Gag-P1 fusion proteins corresponding to the predicted molecular masses 80 and 95 kDa were detected from cells transfected with RNA genomes derived by *in vitro* transcription of pT7-IC-GAG 1 and pT7-IC-GAG 2, respectively. Similarly, an HIV-1 Pol-P1 fusion protein of the predicted molecular mass 85 kDa was immunoprecipitated from cells transfected with RNA derived from the *in vitro* transcription of pT7-IC-POL. These results demonstrate that transfection of the recombinant poliovirus RNA into VV-P1 infected cells results in the expression of appropriate HIV-1-P1 fusion proteins as well as 3D^{pol} related proteins.

**EXAMPLE 2: ENCAPSIDATION AND SERIAL PASSAGE OF
RECOMBINANT POLIOVIRUS NUCLEIC ACID IN WHICH
THE VP2 AND VP3 REGIONS OF THE POLIOVIRUS
GENOME ARE REPLACED WITH A PORTION OF THE HIV-
1 GAG OR POL GENES IN CELLS WITH AN EXPRESSION
VECTOR WHICH EXPRESSES THE POLIOVIRUS CAPSID
PRECURSOR PROTEIN P1**

In order to determine whether transfection of the recombinant poliovirus nucleic acids encoding the HIV-1 *gag* and *pol* genes into VV-P1 infected cells would result in encapsidation of the recombinant poliovirus nucleic acid, the recombinant poliovirus RNA's were transfected into either VV-P1 or wt VV-infected cells, and the encapsidation genomes were isolated as described in Materials and Methods I. The pelleted material was then used to reinfect cells. This procedure was followed by metabolic labeling of viral proteins and incubation with anti-3D^{pol} or HIV-1- antisera (Figures 4A and 4B). Figures 4A and 4B show an analysis of poliovirus- and HIV-1-specific protein expression from cells infected with recombinant poliovirus nucleic acids which were encapsidated and serially passaged with capsid proteins provided by VV-P1. Cells were infected with VV-P1 or wt VV at a multiplicity of infection of 20 and transfected with RNA derived from *in vitro* transcription

of the designated plasmids. The cells were harvested for isolation of encapsidated genomes as described in Materials and Methods I. The pelleted material was used to reinfect cells, which were metabolically labeled, and cell lysates were incubated with the designated antibodies. Immunoreactive proteins were analyzed on SDS-polyacrylamide gels. Figure 4A: Lanes: 1 and 5, cells infected with pelleted material derived from cells infected with wt VV and transfected with RNA derived from pT7-IC-GAG 1; 2 and 6, cells infected with pelleted material derived from cells infected with VV-P1 and transfected with RNA derived from pT7-IC-GAG 1; 3 and 7, cells infected with pelleted material derived from cells infected with wt VV and transfected with RNA derived from pT7-IC-GAG 2; 4 and 8, cells infected with pelleted material derived from cells infected with VV-P1 and transfected with RNA derived from pT7-IC-GAG 2. Figure 4B: Lanes: 1 and 3, cells infected with pelleted material derived from cells infected with wt VV and transfected with RNA derived from pT7-IC-POL; 2 and 4, cells infected with pelleted material derived from cells infected with VV-P1 and transfected with RNA derived from pT7-IC-POL.

The poliovirus 3CD protein was immunoprecipitated from cells infected with pelleted material derived from transfection of the recombinant poliovirus RNA into VV-P1 infected cells. The molecular masses of the HIV-1-P1 fusion proteins immunoprecipitated from the infected cells were consistent with the predicted molecular masses and those observed from expression of the recombinant poliovirus nucleic acid in transfected cells (Figure 2). No 3D^{pol} or HIV-1-P1 proteins were detected from cells infected with material derived from transfection of the chimeric genomes into wt VV-infected cells, demonstrating a requirement for the poliovirus P1 protein for encapsidation of the recombinant poliovirus nucleic acid.

To determine whether the encapsidated recombinant poliovirus nucleic acid could be serially passaged, passage 1 stock of the encapsidated recombinant poliovirus nucleic acid was used to infect cells that had been previously infected with VV-P1. After 24 hours, the encapsidated recombinant poliovirus nucleic acids were isolated as described in Materials and Methods I and subsequently used to reinfect cells which had been previously infected with VV-P1; this procedure was repeated for an additional nine passages. By convention the stocks of serially passaged recombinant poliovirus RNA are referred to as vIC-GAG 1, vIC-GAG 2, or vIC-POL. Cells were infected with passage 9 material and metabolically labeled and the lysates were incubated with antisera to poliovirus 3D^{pol} protein or antibodies to HIV-1 proteins (Figure 4C). In Figure 4C, stocks of the encapsidated recombinant poliovirus nucleic acids were also used to infect cells which had been previously infected with VV-P1 for serial passage of the encapsidated genomes as described in Materials and Methods I. Cells were infected with serially passaged stocks of recombinant poliovirus nucleic acids at passage 9 and metabolically labeled, and cell extracts were incubated with the designated antibodies (ab). Immunoreactive proteins were analyzed on SDS-polyacrylamide gels. Lanes: 1, cells infected with wild-type poliovirus; 2 and 5, cells infected with vIC-GAG 1; 3

and 6, Cells infected with vIC-GAG2; 4 and 7, cells infected with vIC-POL. The positions of molecular mass standards are indicated.

The poliovirus 3CD protein was immunoprecipitated from cells infected with poliovirus and the encapsidated recombinant poliovirus nucleic acids. The HIV-1-Gag-P1 and HIV-1-Pol-P1 fusion proteins were also immunoprecipitated from cells infected with the serially passaged recombinant poliovirus nucleic acids. In contrast, no immunoreactive proteins were detected from cells which were infected with VV-P1 alone and immunoprecipitated with the same antisera (Figure 3).

To determine whether the encapsidated recombinant poliovirus nucleic acids had undergone any significant deletion of genome size as a result of serial passage with VV-P1, RNA isolated from vIC-GAG 1 at passage 14 was analyzed by Northern blotting (Figure 5). Figure 5 shows a Northern blot analysis of RNA isolated from a stock of encapsidated recombinant poliovirus nucleic acids. Virions were isolated by ultracentrifugation from a stock of vIC-GAG 1 at passage 14 and from type 1 Mahoney poliovirus. The isolated virions were disrupted, and the RNA was precipitated, separated in a formaldehyde-agarose gel, and transferred to nitrocellulose. Lanes: 1, RNA isolated from vIC-GAG 1 stock; 2, RNA isolated from poliovirions. Note that the exposure time for the sample in lane 1 of the gel was six times longer than that for lane 2.

For these studies, a riboprobe complementary to nucleotides 671 to 1174 of poliovirus, present in the HIV-1-poliovirus chimeric genomes, was used. RNA isolated from vIC-GAG 1 was compared with RNA isolated from type 1 Mahoney poliovirions. The migration of the RNA isolated from vIC-GAG 1 was slightly faster than that of the wild-type poliovirus RNA, consistent with the predicted 7.0-kb size for RNA from pT7-IC-GAG 1 versus the 7.5-kb size for wild-type poliovirus RNA. Furthermore, a single predominant RNA species from vIC-GAG 1 was detected, indicating that no significant deletions of the RNA had occurred during the serial passages.

Antibody neutralization of recombinant poliovirus nucleic acid encapsidated by VV-P1

To confirm that the recombinant poliovirus nucleic acid RNA passaged with VV-P1 was encapsidated in poliovirions, the capacity of poliovirus-specific antisera to prevent expression of the HIV-1-P1 fusion proteins and poliovirus 3CD protein was analyzed. The results of this experiment are important to exclude the possibility that the recombinant poliovirus nucleic acids were being passaged by inclusion into VV-P1 rather than poliovirions. For these studies, passage 9 material of vIC-GAG 1 was preincubated with preimmune type 1 poliovirus antisera as described in Materials and Methods I. After incubation, the samples were used to infect cells, which were then metabolically labeled, and cell lysates were analyzed for expression of poliovirus- and HIV-1 specific proteins after incubation with anti-3Dpol antisera and pooled AIDS patient sera, respectively (Figure 6). Figure 6 shows neutralization of recombinant poliovirus nucleic acids encapsidated by VV-

P1 with anti-poliovirus antibodies. Cells were infected with a passage 9 stock of vIC-GAG 1 that had been preincubated with anti-poliovirus type 1 antisera or preimmune sera as described in Materials and Methods I. Infected cells were metabolically labeled, cell lysates were incubated with anti-3D^{pol} antibodies (lanes 1 to 3) or pooled AIDS patient sera (lanes 4 and 5), and immunoreactive proteins were analyzed on SDS-polyacrylamide gels. Lanes: 1, cells infected with wild-type poliovirus (no neutralization); 2 and 4, cells infected with vIC-GAG 1 which had been preincubated with preimmune sera; 3 and 5, cells infected with vIC-GAG 1 which had been preincubated with anti-poliovirus type 1 antisera. The positions of molecular mass standards are indicated.

No expression of the poliovirus 3CD or HIV-1-Gag-P1 fusion protein was detected from cells infected with vIC-GAG 1 which had been preincubated with the anti-poliovirus antibodies. Expression of 3CD protein and HIV-1-Gag-P1 fusion protein was readily detected from cells infected with vIC-GAG 1 which had been preincubated with normal rabbit serum (preimmune). These results demonstrate that the recombinant poliovirus nucleic acids were encapsidated by P1 protein provided in *trans* by VV-P1 which could be neutralized by anti-poliovirus antibodies.

Encapsidation of serially passaged recombinant poliovirus nucleic acids by poliovirus

To determine whether the recombinant poliovirus nucleic acid genomes could be encapsidated by P1 protein provided in *trans* from wild-type poliovirus, cells were coinfectd with type 1 Sabin poliovirus and passage 14 stock of vIC-GAG 1. After 24 hours, the coinfectd cells were harvested as described in Materials and Methods I, and the extracted material was serially passaged 10 additional times at a high multiplicity of infection. Cells were infected with passage 10 material of vIC-GAG 1 and type 1 Sabin poliovirus and metabolically labeled, and cell extracts were incubated with antibodies to type 1 Sabin poliovirus (Figure 7A), pooled sera from AIDS patients (Figure 7B), and anti-p24 antibodies (Figure 7C) and the immunoreactive proteins were analyzed on SDS polyacrylamide gels. Lanes: 1, cells infected with type 1 Sabin poliovirus alone; 2, cells infected with material derived from passage 10 of vIC-GAG 1 and type 1 Sabin poliovirus. The positions of relevant proteins are indicated.

Poliovirus capsid proteins were detected from cells infected with type 1 Sabin poliovirus alone and from cells infected with material derived from passaging vIC-GAG 1 with type 1 Sabin poliovirus. No HIV-1 specific proteins were detected from cells infected with type 1 Sabin poliovirus alone. A slight cross-reactivity of the HIV-1-Gag-P1 fusion protein with anti-poliovirus antisera was detected in extracts of cells infected with material derived from passaging vIC-GAG 1 with type 1 Sabin poliovirus (Figure 7A). Although the HIV-1-Gag-P1 fusion protein was clearly detected from cells with type 1 Sabin poliovirus after incubation with pooled AIDS patient sera, some cross-reactivity of the poliovirus capsid proteins were also detected (Figure 7B). To confirm that the HIV-1-Gag-P1 fusion protein

had been immunoprecipitated from extracts of cells infected with material derived from passaging vIC-Gag 1 with type 1 Sabin poliovirus, the extracts were incubated with rabbit anti-p24 antiserum (Figure 7C). Again, detection of the HIV-1-Gag-P1 fusion protein was evident from cells infected with material derived from passaging vIC-GAG 1 with type 1 Sabin poliovirus but not from cells infected with type 1 Sabin alone. Furthermore, HIV-1-Gag-P1 fusion protein expression was detected after each serial passage (1 to 10) of vIC-GAG 1 with type 1 Sabin poliovirus. These results demonstrate that the chimeric recombinant poliovirus nucleic acids can be encapsidated by P1 protein provided in *trans* from type 1 Sabin poliovirus under the appropriate experimental conditions and are stable upon serial passage.

EXAMPLE 3: PRODUCTION OF ANTI-POLIOVIRUS AND ANTI-GAG ANTIBODIES IN MICE IMMUNIZED WITH ENCAPSIDATED RECOMBINANT POLIOVIRUS NUCLEIC ACID CONTAINING A PORTION OF THE HIV-1 GAG GENE

The construction and characterization of chimeric HIV-1 poliovirus nucleic acid in which the HIV-1 *gag* gene was substituted for VP2 and VP3 regions of the poliovirus P1 protein in the infectious cDNA of poliovirus was performed as described previously. Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883. To evaluate both qualitatively and quantitatively the immune responses against HIV-1 *gag* expressed from recombinant poliovirus nucleic acid, BALB/c mice (5 animals in each of three groups) were immunized by parenteral (intramuscular), oral (intra-gastric) or intrarectal routes. The doses were 2.5×10^5 virus PFU poliovirus/mouse for systemic immunization (intramuscular) and 2.5×10^6 PFU poliovirus/mouse for oral immunization. It is important to note that the titer refers only to the type II Lansing in the virus preparation, since the encapsidated recombinant poliovirus nucleic acid alone does not form plaques due to deletion of the P1 capsids. For oral immunization, the antigen was resuspended in 0.5 ml of RPMI 1640 and administered by means of an animal feeding tube (Moldoveanu et al. (1993) *J. Infect. Dis.* 167:84-90). Intrarectal immunization was accomplished by application of a small dose of virus in solution (10 μ l/mouse intrarectally). Serum, saliva, fecal extract and vaginal lavage were collected before immunization, and two weeks after the initial dose of the virus.

Collection of Biological Fluids

Biological fluids were collected two weeks after the primary immunization, and one week after the secondary immunization. The methods for obtaining biological fluids are as follows:

Blood was collected from the tail vein with heparinized glass capillary tubes before and at selected times after immunization. The blood was centrifuged and plasma collected and stored at -70°C.

Stimulated saliva was collected with capillary tubes after injection with carbamyl-choline (1-2µg/mouse). Two µg each of soybean trypsin inhibitor and phenylmethylsulfonyl fluoride (PMSF) was added to the sample followed by clarification by centrifugation at 800 x g for 15 minutes. Sodium azide (0.1% final concentration) and FCS (1% final concentration) was added after clarification and the sample stored at -70°C until the assay.

Vaginal lavages were performed in mice by applying approximately 50 µl sterile PBS into the vagina and then aspirating the outcoming fluid.

Intestinal lavages were performed according to the methods previously described by Elson et al. (Elson, C.O. et al. (1984) *J. Immunol. Meth.* 67:101-108). For those studies, four doses of 0.5 ml lavage solution (isoosmotic for mouse gastrointestinal secretion) was administered at 15 minute intervals using an intubation needle. Fifteen minutes after the last dose of lavage, 0.1 µg of polycarbene was administered by intraperitoneal injection to the anesthetized mouse. Over the next 10 to 15 minutes the discharge of intestinal contents was collected into a petri dish containing a 5 ml solution of 0.1 mg/ml trypsin soybean inhibitor and 5 mM EDTA. The solid material was removed by centrifugation (650 x g for 10 minutes at 4°C) and the supernatant collected. Thirty µl of 100 mM PMSF was then added followed by further clarification at 27,000 x g for 20 minutes at 4°C. An aliquot of 10µl of 0.1% sodium azide and 10% fetal calf serum was added before storage at -70°C.

Fecal Extract was prepared as previously described (Keller, R., and Dwyer, J.E. (1968) *J. Immunol.* 101:192-202).

25 Enzyme-Linked Immunoabsorbant Assay

An ELISA was used for determining antigen-specific antibodies as well as for total levels of immunoglobulins. The assay was performed in 96-well polystyrene microtiter plates (Dynatech, Alexandria, VA). For coating, purified poliovirus (1 µg/well) or HIV specific proteins, or solid phase adsorbed, and affinity-purified polyclonal goat IgG antibodies specific for mouse IgG, IgA or IgM (Southern Biotechnology Associates, Birmingham, AL (SBA)(1µg/well)) were employed. Dilutions of serum or secretions were incubated overnight at 4°C on the coated and blocked ELISA plates and the bound immunoglobulins were detected with horseradish peroxidase-labeled goat IgG against mouse Ig, IgA, IgG, or IgM (SBA). At the end of the incubation time (3 hours at 37°C), the peroxidase substrate 2,2-azino bis. (3-ethylbenzthiazoline) sulfonic acid (ABTS) (Sigma, St. Louis, MO) in citrate buffer pH 4.2 containing 0.0075% H₂O₂ was added. The color developed was measured in a Titertek Multiscan photometer (Molecular Devices, Palo Alto, CA) at 414 nm. To calibrate the total level of mouse IgA, IgG, IgM levels, purified mouse myeloma proteins served as standards. For antigen-specific ELISA, the optical densities

were converted to ELISA units, using calibration curves obtained from optical density values obtained from reference pools of sera or secretions. The calibration curves were constructed using a computer program on either 4-parameter logistic or weighed logit-log models. End point titration values were an alternative way of expressing the results. The fold increase values were calculated by dividing post-immunization by pre-immunization values expressed in ELISA units.

Anti-poliovirus antibodies

The levels of anti-poliovirus antibodies were determined by ELISA at Day 0 (pre-immune), Days 12, and 21 post immunization. A second administration of encapsidated recombinant poliovirus nucleic acid was given by the same route at day 21, and samples were collected 14 days post to second booster and 45 days post second booster. Figures 8A, 8B, and 8C show serum anti-poliovirus antibodies (designated total IgG, representing predominantly IgG, with minor contribution of IgM and IgA) for animals immunized via the intragastric, intrarectal, or intramuscular route. The samples from each of the 5 animals within the group were pooled, and the ELISA was used to determine the amounts of anti-poliovirus antibodies at a 1:20 dilution. A very slight increase in the anti-poliovirus antibodies present in the serum of mice immunized via the intragastric route was observed at Day 45 post booster immunization when compared to the pre-immune levels at Day 0. A clear increase in the serum anti-poliovirus antibodies was observed in the animals immunized via the intragastric or intramuscular route at Day 14 and Day 45 post booster immunization. The levels at Day 14 and 45 post booster immunization were approximately 5-fold over that observed for the background levels at Day 0.

In Figures 9A, 9B, and 9C, IgA anti-poliovirus antibodies present in the saliva of animals immunized with the encapsidated recombinant poliovirus nucleic acids were analyzed. In this case, there was a clear increase in the levels of IgA anti-poliovirus antibodies in animals immunized via the intragastric, intrarectal, or intramuscular route at Day 14 and 45 post booster immunization. In Figures 10A and 10B, IgA anti-poliovirus antibodies from the vaginal lavage samples taken from mice immunized via the intrarectal or intramuscular route were analyzed. In this case, there was a clear increase over the pre-immune values at Day 45 post booster immunization with animals immunized via the intrarectal route. In contrast, there was not a significant increase in the levels of IgA anti-poliovirus antibodies in animals immunized via the intramuscular route. Finally, as shown in Figures 11A, 11B, and 11C, IgA anti-poliovirus antibodies were present in extracts from feces obtained from animals immunized via the intragastric, intrarectal or intramuscular route. In all cases, there was an increase of the IgA anti-poliovirus antibodies at Day 21, Day 14 post booster immunization and Day 45 post booster immunization. Levels were approximately 5-fold over the pre-immune levels taken at Day 0. It is possible that the levels of anti-poliovirus detected have been underestimated due to the possibility that the animals

are also shedding poliovirus in the feces at this time. The shed poliovirus as well as anti-poliovirus antibodies form an immune complex which would not be detected in the ELISA assay.

5 Anti-HIV-1-gag Antibodies

Portions of the same samples that were collected to analyze anti-poliovirus antibodies were analyzed for the presence of anti-HIV-1-gag-antibodies. Figures 12A, 12B, and 12C show the serum levels of total IgG (representing IgG as the major species and IgM and IgA as the minor species) anti-HIV-1-gag antibodies in the serum of animals immunized via the
10 intragastric, intrarectal, or intramuscular route. No consistent increase in the levels of serum antibodies directed against HIV-1-gag antibodies in animals immunized via the intragastric or intrarectal route was observed. This is represented by the fact that there was no increase in the levels above that observed at Day 0 (pre-immune) value. In contrast, there was an
15 increase in the anti-HIV-1-gag antibodies levels in mice immunized via the intramuscular route. On Day 21 post immunization, there was a clear increase over the background value. The levels of anti-HIV-1-gag antibodies in the serum at Days 14 post boost and 45 post boost were clearly above the pre-immune values in the animals immunized via the intramuscular route.

In Figures 13A, 13B, and 13C, IgA anti-HIV-1-gag antibodies present in the saliva of
20 animals immunized via the intragastric, intrarectal or intramuscular route. In this case, there was a clear increase over the pre-immune levels (Day 0) in animals immunized by all three routes of immunization. The highest levels of IgA anti-HIV-1-gag antibodies in the saliva were found at Day 45 post booster immunization. Figures 14A and 14B show a similar pattern for the samples obtained from vaginal lavage of animals immunized via the intrarectal
25 or intramuscular route. In this instance, there was a clear increase at Days 14 and 45 post booster immunization in the levels of IgA anti-HIV-1-gag antibodies from animals immunized via the intrarectal route of immunization. The animals immunized via the intramuscular route exhibited an increase of IgA anti-HIV-1-gag antibodies in vaginal lavage samples starting at Day 12 through Day 21. The levels increased following the booster
30 immunization at Day 21 resulting in the highest levels observed at Day 45 post booster immunization. In Figures 15A, 15B, and 15C, IgA anti-HIV-1-gag antibodies present in fecal extracts obtained from animals immunized via the three different routes were analyzed. In general, there was an increase of the pre-immune levels using all three routes of immunization that was most evident at Days 14 and 45 post booster immunization. The
35 results of these studies clearly establish that administration of the encapsidated recombinant HIV-1-poliovirus nucleic acids via the intragastric, intrarectal, or intramuscular route results in the generation of anti-HIV-1-gag antibodies in serum, saliva, vaginal lavage, as well as fecal extracts. A greater serum anti-HIV-1-gag antibody response was obtained by immunization of the animals via the intramuscular route rather than the intragastric or

intrarectal routes. However, IgA anti-HIV-1-gag antibodies in secretions of animal immunized via all three routes were observed.

EXAMPLE 4: PRODUCTION OF ANTI-POLIOVIRUS ANTIBODIES IN
5 PIGTAIL MACAQUE IMMUNIZED WITH ENCAPSIDATED
RECOMBINANT POLIOVIRUS NUCLEIC ACID
CONTAINING A PORTION OF THE HIV-1 GAG GENE

10 A pigtail macaque was immunized with 5×10^8 PFU of a virus stock of type I
attenuated poliovirus containing the encapsidated recombinant nucleic acid from pT7IC-Gag
#2 (Figure 2). For these studies, intrarectal immunization was performed because of the high
concentration of gut associated lymphoid tissue in the rectum of primates. The virus was
deposited in a volume of 1 ml using a syringe filter with soft plastic tubing and inserted 1
15 inch into the rectum. The analysis of the anti-poliovirus and anti-gag antibodies was as
described in Example 2 except that anti-monkey-specific reagents were substituted for anti-
murine-specific reagents.

 Serum from the macaque prior to immunization (Day 0), 12 days post primary
immunization (12pp), 27 days post primary immunization (27pp) were collected. A second
administration of virus consisting of 1 ml of 5×10^8 PFU given intrarectally and 2.5×10^7
20 PFU of virus administered intranasally at 27 days post primary immunization. Fourteen days
after the second administration of virus (14 days post booster) serum was collected.

 All serum samples were diluted 1:400 in PBS and the levels of IgG anti-poliovirus
antibody were determined by ELISA as described above. As shown in Figure 16, there was a
clear increase in the serum IgG anti-poliovirus antibodies, as measured by OD₄₁₄ in the
25 ELISA, in the immunized macaque at 14 days post booster immunization. The levels were
approximately 10-fold higher than the previous levels (Day 0). This study shows that
intrarectal primary followed by intrarectal-intranasal booster immunization results in clear
increase in the IgG anti-poliovirus antibodies.

30 **MATERIALS AND METHODS II:**

 The following materials and methods were used in Examples 5 and 6:

 All chemicals were purchased from Sigma Chemical Company. Tissue culture media
and supplements were purchased from Gibco/BRL Company. The [³⁵S] Translabel
(methionine/cysteine) and methionine/cysteine-free DMEM were purchased from ICN
35 Biochemicals. Restriction enzymes were obtained from New England Biolabs. The T7 RNA
by the method of Grodberg and Dunn ((1988) *J. Bacteriol.* 170:1245-1253). Synthetic DNA
primers were prepared at the University of Alabama Comprehensive Cancer Center facility or
obtained from Cruachem, Fisher Co. Tri Reagent-LS was obtained from Molecular Research
Center, Inc.

Tissue Culture Cells and Viruses

HeLa T4 and BSC-40 (African green monkey kidney/cell line derived from BSC 1 cells) cell monolayers were grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with 5% fetal calf serum and 1 x GMS-G supplement (complete medium). The stock of the poliovirus type 1 Mahoney was derived from transfection of an infectious cDNA clone of poliovirus obtained from B Semler, University of California at Irvine (Semler, B.L. et al. (1984) *Nucleic Acids Res.* 12:5123-5141). The stock of poliovirus type 1 Sabin was obtained from American Type Culture Collection. The recombinant vaccinia virus VV-PI, which expresses the poliovirus P1 capsid precursor protein upon infection, has also been previously described (Ansardi, D. C. et al. (1991) *J. Virol.* 65:2088-2092). Antisera (recombinant) to HIV-1 p25/24 Gag (Steimer, K.S. et al. (1986) *Virol.* 150:283-290) and a recombinant vaccinia virus vVKI (Karacostas, V. K. et al. (1989) *Proc. Natl. Acad. Sci. (USA)* 86:8964-8967), which expresses the Pr55^{gag} protein upon infection, was obtained through the AIDS Research and Reference Reagent Program. The antisera to 3D^{pol} has been previously described (Jablonski, S.A. et al. (1991) *J. Virol.* 65:4565-4572).

Construction of recombinant poliovirus nucleic acid containing the HIV-1 gag gene

To subclone the HIV-1 recombinant poliovirus genomes, modifications were made to the poliovirus cDNA plasmid pT7-IC, which contains the poliovirus cDNA, and has been described previously (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). A unique Sac I restriction site was generated at the 5' end of the P1 region in the plasmid pT7-IC by a conservative single base change at nucleotide 748 by site-directed mutagenesis to generate the plasmid pT7-IC-Sac I (Sambrook, J. et al. *Molecular Cloning: A Laboratory Manual*, 2nd ed. (Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, 1989). The mutation was confirmed by sequence analysis of ds DNA (Sambrook, J. et al. *Molecular Cloning: A Laboratory Manual*, 2nd ed. (Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, 1989). A unique SnaBI restriction site was then generated in the same plasmid by PCR, at nucleotide 3359, using the following synthetic DNA primers:

5'-CAC-CCC-TCT-CCT-ACG-TAA-CCA-AGG-ATC-3' (SEQ ID NO: 9), and
5'-GTA-CTG-GTC-ACC-ATA-TTG-GTC-AAC-3' (SEQ ID NO: 10). The amplified DNA fragment was precipitated and digested with SnaBI and BstEII. After digestion of the plasmid pT7-IC-Sac I with SnaBI and BstEII, the PCR fragment was ligated into the plasmid. The resultant plasmid was designated pT7-IC-Sac I-SnaBI.

To construct recombinant poliovirus nucleic acid which contains the complete HIV-1 Pr55^{gag} gene, nucleotides 345 to 1837 were amplified from the plasmid pHXB2 (Ratner, L. et al. (1985) *Nature* 313:277-284) by PCR using the following DNA primers:

5'-GGA-GAG-AGA-TGG-GAG-CTC-GAG-CGT-C-3' (SEQ ID NO: 11), and 5'-GCC-CCC-CTA-TAC-GTA-TTG-TG-3' (SEQ ID NO: 12). The DNA fragment was ligated into

the plasmid pT7-IC-Sac I-SnaBI after digestion of the fragment DNA and pT7-IC-Sac I-SnaBI with Sac I and SnaBI DNA sequencing confirmed that the translational reading frame was maintained between the foreign gene and poliovirus. The final construct was designated as pT7-IC-Pr55gag

5 A second recombinant poliovirus nucleic acid containing the HIV-1 gag gene was constructed to position nucleotides 1-949 of the poliovirus genome 5' to the HIV-1 gag gene. The following primers were designed to amplify a DNA fragment from the plasmid pT7-IC from a unique EcoRI site, located upstream of the T7 RNA polymerase promoter, to nucleotide 949: 5'-CCA-GTG-AAT-TCC-TAA-TAC-GAC-TCA-CTA-TAG-GTT-
10 AAA-ACA-GC-3' (SEQ ID NO: 13) and 5'-CTC-TAT-CCT-GAG-CTC-CAT-ATG-TGT-CGA-GCA-GTT-TTT-GGT-TTA-GCA-TTG-3' (SEQ ID NO: 14). The primers were designed to include a 2A protease cleavage site (tyrosine-glycine amino acid pair (underlined) preceded by six wild-type amino acids: Thr-Lys-Asp-Leu-Thr-Thr-Tyr-Gly) (SEQ ID NO: 15), corresponding to the authentic 2A cleavage site in the 3D^{pol} gene at nucleotide 6430 in the poliovirus genome, followed by a Sac I restriction site at the 3' end of the VP4 gene in the amplified fragment. The DNA fragment was ligated into pT7-IC-Pr55gag after digestion with EcoRI and Sac I. The final construct was designated pT7-IC-Pr55gag(VP4/2A).

The construction and characterization of the pT7-IC-Gag 1 has been described in
20 previous studies (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). Briefly, pT7-IC-Gag 1 was constructed by substitution of nucleotides 718 to 1549 of the HIV-1 gag gene (amplified using PCR) for the P1 coding region between nucleotides 1174 and 2470 in the infectious cDNA plasmid pT7-IC. This substitution encompasses most of the VP2 and VP3 capsid sequences while maintaining the VP4 and VP1
25 coding regions.

Encapsidation and serial passage of recombinant poliovirus nucleic acid containing the HIV-1 gag gene

The encapsidation and serial passage of recombinant poliovirus nucleic acid using
30 VV-P1 has been previously described (Morrow, C.D. et al. (1994) "New Approaches for Mucosal Vaccines for AIDS: Encapsidation and Serial Passage of Poliovirus Replicons that Express HIV-1 Proteins Upon Infection" *AIDS Res. and Human Retroviruses* 10(2); Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). Briefly, HeLa T4 cells were infected with 5 PFU/cell of VV-P1, which expresses the poliovirus capsid precursor protein P1. At 2 hours
35 post-infection, the cells were transfected using the DEAE-Dextran method with RNA transcribed from the chimeric genomes *in vitro* as previously described (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883; Pal-Ghosh, R. et al. (1993) *J. Virol.* 67:4621-4629; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). The cultures were harvested at 24 hours post-transfection by detergent lysis, overlaid on a 30% sucrose cushion (30% sucrose, 30 mM

Tris pH 8.0, 1% Triton X-100, 0.1 M NaCl), and centrifuged in a Beckman SW55Ti rotor at 55,000 rpm for 1.5 hours (Ansardi, D. C. et al. (1993) *J. Virol.* 67:3684-3690; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). The supernatant was discarded and the pellet washed under the same conditions in a low salt buffer (30mM Tris pH 8.0, 0.1 M NaCl) for an additional 1.5 hours. The pellets were then resuspended in complete DMEM and used for serial passage immediately or stored at -70° C until used

For serial passage of the encapsidated recombinant poliovirus nucleic acid and generation of virus stocks, BSC-40 cells were first infected with 10-20 PFU/cell of VV-P1. At 2 hours post-infection, the cells were infected with passage 1 of the encapsidated recombinant poliovirus nucleic acid. The cultures were harvested at 24 hours post-infection by three successive freeze/thaws, sonicated, and clarified by low speed centrifugation at 14,000 x g for 20 minutes. The supernatants were then stored at -70°C or used immediately for additional passages following the same procedure.

15 Metabolic labeling and immunoprecipitation of viral proteins from infected cells

To metabolically label proteins from infected cells, the cultures were starved for methionine/cysteine at the times indicated post-infection by incubation in DMEM minus methionine/cysteine for 30 minutes. At the end of this time, [³⁵S] Translabel was added for an additional one hour. Cultures were then processed for immunoprecipitation of viral proteins by lysing the cells with RIPA buffer (150 mM NaCl, 10 mM Tris pH 7.8, 1% Triton X-100, 1% sodium deoxycholate, 0.2% sodium dodecyl sulfate). Following centrifugation at 14,000 x g for 10 minutes, the designated antibodies were added to the supernatants which were then incubated at 4°C for 24 hours. The immunoprecipitates were collected by addition of 100µl protein A-Sepharose (10% weight/volume in RIPA buffer). After a 1 hour incubation at room temperature, the protein A-Sepharose beads were collected by brief centrifugation and washed 3 times with RIPA buffer. The bound material was eluted by boiling 5 minutes in gel sample buffer (62.5 mM Tris pH 6.8, 2% SDS, 20% glycerol, 0.05% bromophenol blue, and 0.7M 13-mercaptoethanol). The proteins were analyzed by SDS-polyacrylamide gel electrophoresis and radiolabeled proteins were visualized by fluorography using sodium salicylate as previously described (Ansardi, D. C. et al. (1993) *J. Virol.* 67:3684-3690; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). The immunoprecipitated proteins were quantitated by phosphorimager where indicated (Molecular Dynamics).

35 Nucleic acid hybridization of RNA

Total cellular RNA was prepared from cells transfected with equivalent amounts of *in vitro* transcribed RNA as described by the manufacturer using Tri Reagent-LS (Molecular Research Center, Inc.). The amounts of full length RNA transcripts were estimated by agarose gel electrophoresis prior to transfection (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-

1883). The RNA was then denatured, separated on a formaldehyde-1.0% agarose gel, and transferred from the gel to a nitrocellulose filter by capillary action. Equivalent amounts of RNA, as measured by levels of rRNA, were loaded into each lane of the gel. For analysis of encapsidated recombinant poliovirus RNA, the RNA was isolated from virions (Ricco-Hesse, R. M. et al. (1987) *Viol.* 160:311-322) which had been concentrated through a sucrose cushion as previously described (Ansardi, D. C. et al. (1993) *J. Virol.* 67:3684-3690; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). The RNA was denatured and spotted onto nitrocellulose using a dot blot apparatus according to established protocols (Sambrook, J. et al. *Molecular Cloning: A Laboratory Manual*, 2nd ed. (Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, 1989). The RNA was immobilized onto the nitrocellulose by baking in a vacuum oven at 80°C for 1 hour.

The conditions for prehybridization, hybridization and washing of RNA immobilized onto nitrocellulose were as described previously (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883; Pal-Ghosh, R. et al. (1993) *J. Virol.* 67:4621-4629; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). Briefly, the blot was prehybridized in hybridization buffer (50% deionized formamide, 6X SSC, 1% SDS, 0.1% Tween 20, and 100 µg/mL yeast tRNA). The blot was then incubated in hybridization buffer containing 1×10^6 cpm/mL of a [32 P] labeled riboprobe complementary to nucleotides 671-1174 of the poliovirus genome (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883; Pal-Ghosh, R. et al. (1993) *J. Virol.* 67:4621-4629; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). After hybridization, the blot was washed two times with 0.1 x SSC/ 0.1 % SDS at room temperature and at 65°C. The blot was then exposed to X-ray film with an intensifying screen. The levels of RNA from each sample were quantitated by phosphorimager (Molecular Dynamics).

Passage of recombinant poliovirus nucleic acid containing the HIV-1 gag gene with type 1 attenuated poliovirus

Virus stocks of encapsidated recombinant poliovirus nucleic acid containing HIV-1 gag gene were serially passaged with wild-type poliovirus as previously described (Morrow, C.D. et al. (1994) "New Approaches for Mucosal Vaccines for AIDS: Encapsulation and Serial Passage of Poliovirus Replicons that Express HIV-1 Proteins Upon Infection" *AIDS Res. and Human Retroviruses* 10(2); Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). Briefly, BSC-40 cells were co-infected with 10 PFU/cell of type 1 Sabin poliovirus and a virus stock of encapsidated recombinant poliovirus nucleic acid at pass 21. The infected cells were harvested at 24 hours post-infection by three successive freeze/thaws, sonicated, and clarified by low speed centrifugation. Approximately one-half of the supernatant was used for serial passaging by re-infection of BSC-40 cells. After 24 hours, the cultures were harvested as described above and the procedure was repeated for an additional 2 serial passages.

EXAMPLE 5: CONSTRUCTION, EXPRESSION, AND REPLICATION OF RECOMBINANT POLIOVIRUS NUCLEIC ACIDS CONTAINING THE ENTIRE HIV-1 GAG GENE

5 To further define the requirements of the P1 region for the replication and encapsidation of poliovirus RNA, the complete *gag* gene of HIV-1 was substituted for the P1 capsid coding sequences. For these studies the plasmid pT7-IC (Figure 17A), which contains the promoter sequences for T7 RNA polymerase positioned 5' to the complete poliovirus cDNA, was used (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). A unique *Sal*I restriction
10 site is located after the poly (A) tract that can be used to linearize the cDNA before *in vitro* transcription; the RNA transcripts from this cDNA are infectious upon transfection into tissue culture cells (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). In order to substitute the entire P1 capsid region with the HIV-1 *gag* gene, a unique *Sac*I restriction site was generated at nucleotide 748, immediately following the translational start site of poliovirus. A unique
15 *Sna*BI restriction site was generated at nucleotide 3359, which is positioned eight amino acids prior to the 2A protease cleavage site (tyrosine-glycine) located at nucleotide 3386; previous studies have suggested a requirement for the amino acid at the P4 position for autocatalytic processing of the polyprotein by the 2A protease (Harris, K. et al. (1990) *Sem. in Virol.* 1:323-333). The resultant plasmid, pT7-IC-*Sac*I-*Sna*BI was then used for insertion
20 of the HIV-1 *gag* gene. pT7-IC-Pr55^{gag} (Figure 17B) was constructed by insertion of the complete HIV-1 *gag* gene from nucleotides 345 to 1837; the *Sac*I and *Sna*BI restriction sites were introduced at the 5' and 3' ends of the gene. Substitution of the entire P1 region from the translational start site of poliovirus to the 2A protease (3386), which autocatalytically cleaves from the polyprotein upon translation (Toyoda, H. et al. (1986) *Cell* 45:761-770), results in
25 expression of Pr55^{gag} protein after proteolytic processing of the polyprotein.

Naturally occurring defective interfering (DI) genomes of poliovirus contain heterologous deletions of the P1 coding region that encompass the VP3, VP1 and VP2 capsid sequences. All known poliovirus DI genomes maintain an intact VP4 coding region (Kuge, S. et al. (1986) *J. Mol. Biol.* 192:473-487). A second recombinant poliovirus nucleic acid
30 was generated in which the *gag* gene was substituted in frame for the VP2, VP3 and VP1 capsid sequences, from nucleotides 949 to 3359 to maintain the VP4 coding region. For this construct, a DNA fragment was amplified by PCR from the plasmid pT7-IC containing sequences encoding VP4 followed by the codons for eight amino acids containing a tyrosine-glycine amino acid pair. Substitution of the *Eco*RI to *Sac*I fragment into
35 pT7-IC-Pr55^{gag} results in the final plasmid, pT7-IC-Pr55^{gag} (VP4/2A), which contains the VP4 coding sequences fused in-frame at the 5' end of the complete *gag* gene (Figure 17C). In each construct, the insertion of HIV-1 *gag* gene sequences maintains the translational reading frame with poliovirus.

Poliovirus and HIV-1-specific protein expression from the recombinant poliovirus nucleic acids which contain the HIV-1 *gag* gene was analyzed after transfection of recombinant poliovirus RNA into cells which had been previously infected with VV-P1 (Figures 18A and 18B). Briefly, Cells were infected with VV-P1 at a multiplicity of infection of 5. At 2 hours post infection, the cells were transfected with RNA derived from *in vitro* transcription of the designated plasmids. Cells were metabolically labeled, and cell extracts were incubated with the antibodies indicated and immunoreactive proteins were analyzed on SDS-polyacrylamide gels: (Figure 18A) Lane 1, mock-transfected cells; Lane 2, cells transfected with RNA derived from pT7-IC-Pr55^{gag}; Lane 3, cells transfected with RNA derived from pT7-IC-Pr55^{gag}(VP4/2A); Lane 4, cells transfected with RNA derived from pT7-IC-Gag 1; Lane 5, cells infected with type 1 Mahoney poliovirus at a multiplicity of infection of 30. (Figure 18B): Lane 1, mock-transfected cells; Lane 2, cells transfected with RNA derived from pT7-IC-Pr55^{gag}; Lane 3, cells transfected with RNA derived from pT7-IC-Pr55^{gag}(VP4/2A); Lane 4, cells infected with vVK1 at a multiplicity of infection of 10; Lane 5, cells transfected with RNA derived from pT7-IC-Gag 1. The molecular mass standards and positions of relevant proteins are indicated.

Under the conditions for metabolic labeling, the 3CD protein, which is a fusion between the 3C^{pro} and 3D^{pol} proteins, is the predominant 3D containing viral protein detected from poliovirus-infected cells (Porter, D.C. et al (1993) *Virus. Res.* 29:241-254). A protein with an approximate molecular mass of 72 kDa, corresponding to the 3CD protein of poliovirus, was detected from cells transfected with RNA from pT7-IC-Pr55^{gag} and pT7-IC-Pr55^{gag}(VP4/2A) (Figure 18A, lanes 2 and 3), but not from mock-transfected cells (Figure 18A, lane 1). The 3CD protein was also immunoprecipitated from cells transfected with RNA derived from pT7-IC-Gag 1 (Figure 18A, lane 4), which was used as a positive control for transfections in these studies (Porter, D.C. et al. (1993) *J. Virol.* 3712-3719).

For analysis of the expression of HIV- 1 Gag protein, the extracts were incubated with antip25/24 antibodies (Figure 18B). A lysate from cells infected with the recombinant vaccinia virus vVK1, which contains the HIV-1 gene sequences encoding the complete *gag* and *pol* genes, was used as a control for Pr55^{gag} protein expression (Karacostas, V.K. et al. (1989) *Proc. Natl. Acad. Sci. (USA)* 86:8964-8967). A protein with an apparent molecular mass of 55 kDa that co-migrated with protein immunoprecipitated from cells infected with vVK1 (Figure 18B, lane 4) was detected from cells transfected with RNA from pT7-IC-Pr55^{gag} and pT7-IC-Pr55^{gag}(VP4/2A) (Figure 18B, lanes 2 and 3). In addition, a protein of higher molecular mass was immunoprecipitated from cells transfected with RNA from pT7-IC-Pr55^{gag}(VP4/2A) (Figure 18B, lane 3). This protein probably is a VP4-Pr55^{gag} precursor protein.

The replication of the transfected RNA derived from the recombinant poliovirus nucleic acid was also analyzed by Northern blot (Figures 19A and 19B). HeLa T4 cells were transfected with RNA transcribed *in vitro* from pT7-IC-Pr55^{gag}, pT7-IC-Pr55^{gag}(VP4/2A)

and pT7-IC-Gag 1. At 9 hours postransfection, total cellular RNA was prepared, separated in a 1% formaldehyde-agarose gel, blotted onto nitrocellulose and analyzed using a riboprobe complementary to nucleotides 671-1174 of the poliovirus genome. (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883; Pal-Ghosh, R. et al. (1993) *J. Virol.* 67:4621-4629; Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719) (Figure 19A) The order of the samples is indicated. The migration of RNA of the predicted size, which was derived from *in vitro* transcription of pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A), is indicated by an arrow. The asterisk indicates the migration of RNA of the expected size which was derived from pT7-IC-Gag 1 (Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). The radioactivity of the Northern blot was

quantitated using phosphorimager.

The migration of RNA from pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A) transfected cells was slightly faster on the formaldehyde-agarose gel than RNA from pT7-IC-Gag 1, which is consistent with the predicted 6.3-6.4 kb size for RNA from pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A) versus the 7.0 kb size for RNA from pT7-IC-Gag 1 (Figure 19A). Quantitation of the major bands of radioactivity from each sample by phosphorimager indicated that the values for pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A) were similar although the amounts of RNA detected from both recombinant poliovirus nucleic acids were lower than that for RNA obtained from pT7-IC-Gag 1 (Figure 19B). Together, these results demonstrate that the RNA from pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A) replicate to similar levels in transfected cells.

**EXAMPLE 6: ENCAPSIDATION AND SERIAL PASSAGE OF
RECOMBINANT POLIOVIRUS NUCLEIC ACID
CONTAINING THE ENTIRE HIV-1 GAG GENE**

Cells were infected with VV-P1 and then transfected with RNA transcribed *in vitro* from pT7-IC-Pr55gag, pT7-IC-Pr55gag(VP4/2A) and pT7-IC-Gag 1. The encapsidated recombinant poliovirus genomes were passaged in cells which had been previously infected with VV-P1 for a total of 21 serial passes. Consistent with the nomenclature used herein, the encapsidated virus stocks of pT7-IC-Pr55gag and pT7-IC-Pr55gag(VP4/2A) are referred to as vIC-Pr55gag and vIC-Pr55gag(VP4/2A), respectively.

For analysis of poliovirus and HIV-1-specific protein expression, pass 21 virus stocks of encapsidated recombinant poliovirus nucleic acid were used to infect cells. After metabolic labeling, lysates from the cells were incubated with anti-3Dpol and anti-p24 antibodies (Figure 20). With reference to Figure 20, cells were transfected with RNA derived from *in vitro* transcription of the designated plasmids at 2 hours post-infection with VV-P1. Encapsidated genomes were harvested from cells as described in Materials and Methods II and used to re-infect cells which had been previously infected with VV-P1. The encapsidated recombinant poliovirus genomes were subsequently serially passaged in VV-P1-infected cells

for 21 serial passes. Cells were infected with virus stocks at pass 21 and metabolically labeled. Cell lysates were incubated with the designated antibodies and immunoreactive proteins were analyzed SDS-polyacrylamide gel; Lanes 1 and 6, mock-infected cells; Lanes 2 and 7, cells infected with vIC-Pr55gag; Lanes 3 and 8, cells infected with vIC-Pr55gag(VP4/2A); Lanes 4 and 9, cells infected with vIC-Gag1; Lane 5, cells infected with type 1 Mahoney poliovirus; Lane 10, cells infected with vVK1. The molecular mass standards and positions of relevant proteins are indicated.

Although the 3CD protein was detected from each of the recombinant poliovirus nucleic acid virus stocks, decreased levels of 3CD protein were consistently detected from cells infected with virus stocks of vIC-Pr55gag (Figure 20, lane 2) as compared to cells infected with virus stocks of vIC-Pr55gag(VP4/2A) (Figure 20, lane 3) and vIC-Gag 1 (Figure 20, lane 4). Upon incubation of the lysates with anti-p24 antibodies, a protein with an apparent molecular mass of 55 kDa was detected from the vIC-Pr55gag (Figure 20, lane 7) and vIC-Pr55gag(VP4/2A) (Figure 20, lane 8) virus stocks; this protein co-migrated with Pr55gag expressed from cells infected with the recombinant vaccinia virus vVK1 (Figure 20, lane 10) (Karacostas, V. et al. (1989) *Proc. Natl. Acad. Sci. (USA)* 86:8964-8967). Again, infection of cells with the vIC-Pr55gag(VP4/2A) virus stock resulted in an increased level of the 55 kDa protein, compared to cells infected with vIC-Pr55gag. Consistent with previous studies, vIC-Gag 1 expressed an 80 kDa Gag-P1 fusion protein in infected cells (Figure 20, lane 9) (Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719).

Since it has been demonstrated that after transfection that RNA from each of the recombinant poliovirus nucleic acids resulted in similar levels of replication and protein expression, detection of reduced levels of protein expression from cells infected with vIC-Pr55gag as compared to vIC-Pr55gag(VP4/2A) could be the result of a difference in infectivity (i.e., interaction with receptor, uncoating) between the recombinant poliovirus nucleic acids. To address this question, RNA was isolated from equivalent amounts of vIC-Pr55gag and vIC-Pr55gag(VP4/2A) virus stocks, which had been serially passaged with VV-P1 for 21 passes. Serial dilutions of the RNA were then spotted onto nitrocellulose and analyzed using a riboprobe as described in Materials and Methods II. Quantitation of the radioactivity from each sample by phosphorimagery indicated values from vIC-Pr55gag(VP4/2A) virus stocks which were approximately 15 times higher than the values obtained for RNA from vIC-Pr55gag. The results of these studies corroborate the differences in expression of 3CD and HIV-1 Gag protein observed for the recombinant poliovirus nucleic acids. To address the possibility that the recombinant poliovirus nucleic acids might have differences in infectious potential, cells were infected with equivalent amounts of encapsidated recombinant poliovirus nucleic acids, as determined by RNA hybridization, and metabolically labeled followed by immunoprecipitation with anti-3DPol antibodies (Figure 21A). Equivalent amounts of a 72 kDa protein, corresponding to the 3CD protein, were detected from each of the recombinant poliovirus nucleic acid virus stocks. Quantitation of

the radioactivity from each sample by phosphorimagery confirmed that the levels of 3CD were similar.

With reference to Figure 21A, cells were infected with normalized amounts of encapsidated poliovirus nucleic acid virus stocks and metabolically labeled. Cells lysates
5 were incubated with the designated antibodies and immunoreactive proteins were analyzed on an SDS-polyacrylamide gel: Lane 1, mock infected cells; Lane 2, cells infected with vIC-Pr55^{gag} recombinant poliovirus stock; Lane 3, cells infected with vIC-Pr55^{gag}(VP4/2A) recombinant poliovirus stock; Lane 4, cells infected with vIC-Gag1 recombinant poliovirus stock. With reference to Figure 21B, equivalent amounts of each of the recombinant
10 poliovirus stocks were serially passaged in VV-P1-infected cells for 2 passes as described in Materials and Methods II. Cells were infected with material derived from passes 1 and 2 and metabolically labeled. Cells lysates were incubated with the designated antibodies and immunoreactive proteins were analyzed on an SDS-polyacrylamide gel; Lane U, mock-
15 infected cells; Lane 1, cells infected with material from pass 1 of vIC-Pr55^{gag} with VV-P1; Lane 3 cells infected with material from pass 1 of vIC-Pr55^{gag}(VP4/2A) with VV-P1; Lane 4, cells infected with material from pass 2 of vIC-Pr55^{gag}(VP4/2A) with VV-P1; Lane 5, cells infected with material from pass 1 of vIC-Gag 1 with VV-P1; Lane 6, cells infected with material from pass 2 of vIC-Gag 1 with VV-P1; Lane 7, cells infected with type 1 Mahoney poliovirus. The molecular mass standards and positions of relevant proteins are indicated.

20 To determine whether the decreased levels of RNA isolated from the vIC-Pr55^{gag} virus stock at pass 21 as compared to the vIC-Pr55^{gag}(VP4/2A) and vIC-Gag 1 virus stocks were attributable to differences in the efficiency of encapsidation of RNA which contains the VP4 coding sequences versus the encapsidation of RNA which has a complete deletion of the P1 region, cells which had been previously infected with VV-P1 were infected with
25 normalized amounts of each of the encapsidated recombinant poliovirus nucleic acid virus stocks. After 24 hours, complete cell lysis had occurred and the supernatant was processed as described in Materials and Methods II; one additional passage was performed in cells previously infected with VV-P1. For analysis of protein expression from the serially
30 passaged material, cells were infected with material from passages 1 and 2, metabolically labeled, and the cell lysates were incubated with anti-3D^{pol} antibodies (Figure 21B). Similar amounts of the 3CD protein were detected from each of the passages of equivalent amounts of vIC-Pr55^{gag} (Figure 21B, lanes 1 and 2), vIC-Pr55^{gag}(VP4/2A) (Figure 21B, lanes 3 and 4) and vIC-Gag 1 recombinant poliovirus nucleic acid virus stocks (Figure 21B, lanes 5 and 6) with VV-P1. Thus, the reduced levels of RNA and 3CD protein expression detected from the
35 vIC-Pr55^{gag} recombinant poliovirus nucleic acid virus stocks as compared to vIC-Pr55^{gag}(VP4/2A) and vIC-Gag 1 after 21 serial passes with VV-P1 (Figure 20) were not apparent after passage of the recombinant poliovirus nucleic acids with VV-P1 for 2 serial passes.

Since all known DIs of poliovirus contain an intact VP4 coding region, it was examined whether the recombinant poliovirus nucleic acid which contains the VP4 coding sequences might have an advantage if the recombinant poliovirus nucleic acid had to compete with the wild type genome for capsid proteins. To determine whether vIC-Pr55^{gag} and vIC-Pr55^{gag}(VP4/2A) could also be maintained upon passage with wild-type poliovirus, cells were co-infected with equal amounts of either the vIC-Pr55^{gag}, vIC-Pr55^{gag} (VP4/2A) or vIC-Gag 1 and type 1 Sabin poliovirus. After 24 hours, complete cell lysis had occurred and the supernatant was processed as described in Materials and Methods II; two additional passages were performed. Cells were infected with material from each serial passage, metabolically labeled and the cell extracts were incubated with antibodies to p24/25 protein (Figure 22). With reference to Figure 22, cells were co-infected with equal amounts of either the vIC-Pr55^{gag}, vIC-Pr55^{gag} (VP4/2A) or vIC-Gag 1 and type 1 Sabin poliovirus. The cells were harvested at 24 hours post-infection and the supernatant was processed as described in Materials and Methods II; two additional passages were performed. Cells were infected from each of the serial passages and metabolically labeled. The cell lysates incubated with the designated antibody and immunoreactive proteins were analyzed on an SDS-polyacrylamide gel: Lane U, uninfected cells; Lanes 1, 2 and 3, cells infected with material derived from the indicated passes of vIC-Pr55^{gag} with type 1 Sabin poliovirus; Lanes 4, 5 and 6, cells infected with material derived from the indicated passes of vIC-Pr55^{gag}(VP4/2A) with type 1 Sabin poliovirus; Lanes 7, 8 and 9, cells infected with material derived from the indicated passes of vIC-Gag 1 with type 1 Sabin poliovirus; Lane PV, cells infected with type 1 Sabin poliovirus. Each passage is denoted as follows: P1, pass 1; P2, pass 2; and P3, pass 3. The molecular mass standards and positions of relevant proteins are indicated.

No HIV-1-specific protein was cells infected with type 1 Sabin poliovirus alone (Figure 22, lane PV); the 80 kDa gag-P1 fusion protein was detected from cells infected with material from passages 1, 2 and 3 of the vIC-Gag 1 recombinant poliovirus nucleic acid and wild-type poliovirus (Figure 22, lanes 7-9) (Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719). Upon serial passage of vIC-Pr55^{gag} (Figure 22, lanes 1-3) and vIC-Pr55^{gag}(VP4/2A) (Figure 22, lanes 4-6) virus stocks with type 1 Sabin, a protein which migrated at approximately 55 kDa was detected from cells infected with material from passages 1, 2, and 3. There was no consistent difference detected between the levels of Pr55^{gag} expression from either recombinant poliovirus nucleic acid. Thus, the presence or absence of the VP4 coding region did not effect the capability of the recombinant poliovirus nucleic acid to compete with the wild-type poliovirus genomes for the P1 protein that was evident after three serial passages.

The construction and characterization of a first poliovirus genome which contains the complete 1.5 kb gag gene of HIV-1 substituted for the entire P1 region, and a second poliovirus genome in which the gag gene is positioned 3' to the VP4 coding region of the P1 capsid region are described herein. Transfection of RNA from each of the constructs into cells resulted in similar levels of protein expression and RNA replication. Both genomes

were encapsidated upon transfection into cells previously infected with VV-P1. Serial passage of the recombinant poliovirus nucleic acids with VV-P1 resulted in the production of virus stocks of each of the encapsidated genomes. Analysis of the levels of encapsidated recombinant poliovirus nucleic acids after extended serial passage revealed that the recombinant poliovirus nucleic acids which contain the VP4 coding region were present at higher levels in the encapsidated virus stocks than the recombinant poliovirus nucleic acids which contain the *gag* gene substituted for the entire P1 region; no difference was detected in the levels of encapsidation of either recombinant poliovirus genome following limited serial passages in the presence of VV-P1 or Sabin type 1 poliovirus. The results of this study are significant because this is the first demonstration that poliovirus genomes which contain a foreign gene substituted for the entire P1 region can be encapsidated by P1 provided in *trans*.

Although the presence of the VP4 coding region was not absolutely required for RNA encapsidation, it was evident that recombinant poliovirus nucleic acids which contain a complete substitution of the P1 region with the HIV-1 *gag* gene were encapsidated less efficiently than recombinant poliovirus nucleic acids which maintain the VP4 coding sequences (nucleotides 743 to 949) positioned 5' to the *gag* gene. When RNA derived from each of the encapsidated recombinant poliovirus nucleic acid virus stocks after 21 serial passes with VV-P1 was isolated and quantitated by nucleic acid hybridization, the RNA from vIC-Pr55^{gag}(VP4/2A) and vIC-Gag 1 recombinant poliovirus nucleic acid virus stocks, which contained VP4, were present at levels that were 15 and 50 times higher, respectively, than RNA from vIC-Pr55^{gag} virus stocks. Although it is clear from these results that VP4 is not required for encapsidation, the presence of VP4 might enhance RNA encapsidation. Since limited passage of equivalent amounts of each of the recombinant poliovirus nucleic acid virus stocks with VV-P1 indicated no significant difference in the encapsidation of recombinant poliovirus nucleic acids containing VP4 versus recombinant poliovirus nucleic acids which contain a deletion of the entire P1 coding region, it was possible that the effect of VP4 on encapsidation would be more apparent if the recombinant poliovirus RNA had to compete with the wild-type genomes for the P1 capsid protein. This situation would be analogous to the encapsidation of defective interfering (DI) genomes in that the defective genome must compete effectively with the wild-type genome to be maintained in the virus stock. However, it was determined that RNA from vIC-Pr55^{gag} and vIC-Pr55^{gag}(VP4/2A) was maintained in virus stocks for 3 serial passages in the presence of type 1 poliovirus. Thus, during limited serial passage the recombinant poliovirus genomes did compete effectively with type 1 Sabin poliovirus RNA for capsid proteins.

Using the complementation system described herein, it is possible to substitute the entire P1 region with at least 1.5 kb of foreign DNA. One feature of the expression system described herein is that the foreign protein is expressed as a polypeptide which is processed by 2A^{pro}. Thus, it is possible to express foreign proteins in a native conformation from poliovirus genomes if the residual amino acids at the amino or carboxy termini do not

interfere with proper folding. Preliminary experiments have demonstrated the 55 kDa HIV-1 Gag protein expressed from poliovirus recombinant poliovirus nucleic acids is biologically active (i.e. formation of virus-like particles). If the exact protein sequence is required for protein function, the desired protein can be expressed using internal ribosomal entry sites positioned within the recombinant poliovirus nucleic acid.

MATERIALS AND METHODS III:

The following materials and methods were used in Examples 7, 8, and 9:

10 Plasmid Constructions

All manipulation of recombinant DNA was carried out according to standard procedures (Maniatis, T. et al. Molecular Cloning: A Laboratory Manual (Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York, 1982). The starting plasmid for these studies, pT7-IC, contains the entire full-length poliovirus infectious cDNA positioned immediately downstream from the phage T7 promoter (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). The full-length cDNA encoding CEA (shown in SEQ ID NO: 16, the amino acid sequence of CEA is shown in SEQ ID NO: 17), subcloned into pGEM plasmid (Beauchemin, N. et al. (1987) *Mol. Cell. Biol.* 7:3221-3230), was obtained from Dr. David Curiel, University of Alabama at Birmingham (originally obtained from Dr. Judy Kantor, NIH, Bethesda, MD).

For construction of the backbone poliovirus vector used for insertion of the carcinoembryonic antigen (CEA) gene, two independent PCR reactions were performed. The first was used to amplify the region from nucleotides 1 to 743 of the poliovirus genome using the following PCR primers: 5'-CCA-GTG-AAT-TCC-TAA-TAC-GAC-TAC-CTA-TAG-GTT-AAA-ACA-GC-3' (5' primer) (SEQ ID NO: 18) and 5'-GA-TGA-ACC-CTC-GAG-ACC-CAT-TAT-G-3' (3' primer) (SEQ ID NO: 19).

A second set of PCR primers were designed to amplify a region of the poliovirus genome from 3370 to 6117. The PCR primers were designed so that a unique *Sna*BI restriction site would be created 12 nucleotides from the end of the *P1* gene, resulting in an additional four amino acids upstream from the tyrosine-glycine cleavage site. For subsequent subcloning, the PCR product was digested with *Sna*BI and *Bgl*II, which cuts at nucleotide 5601 in the poliovirus genome. The PCR primers used were as follows: 5'-CCA-CCA-AGT-ACG-TAA-CCA-CAT-ATG-G (5' primer) (SEQ ID NO: 20) and 5'-GTG-AGG-ACTG-CT-GG-3' (3' primer) (SEQ ID NO: 21).

The conditions for PCR were as follows: 1 min at 94°C, 3 min at 37°C, and 3 min at 72°C. After 30 cycles, a 7-min incubation at 72°C was included prior to cessation of the PCR reaction. PCR reactions were extracted successively with phenol:chloroform (1:1) and chloroform:isoamyl alcohol (24:1), and then DNA was precipitated with ethanol. After collection of the precipitate by centrifugation, the DNA was dried and resuspended in water.

The DNA was then digested with the appropriate restriction endonuclease enzymes at the 5' and 3' end of the PCR-amplified products.

Construction of pT7-IC-CEA-sig-

5 To obtain a signal minus version of the CEA gene, PCR was used to amplify a region from the CEA cDNA. The primers used for this PCR reaction were as follows: 5'-CAC-CAC-TGC-CCT-CGA-GAA-GCT-CAC-TAT-TG-3' (5' primer) (SEQ ID NO: 22) and 5'-CAC-CAC-TGC-CCT-CGA-GAA-GCT-CAC-TAT-TG-3' (3' primer) (SEQ ID NO: 23).

10 The DNA primers were chosen to create an XhoI site at the 5' end and a SnaBI site at the 3' terminus of the amplified DNA. The length of the amplified DNA was approximately 100 base pairs less than that of the full-length amplified product for the CEA DNA, corresponding to a loss of 34 amino acids from the amino terminus representing the signal sequence. The conditions for PCR and isolation of the amplified product are as described in Materials and Methods III. Prior to ligation, the amplified product was digested with XhoI
15 and SnaBI.

The plasmid pT7-IC was digested with EcoRI and BglII. The DNA fragment which contains the poliovirus genome from nucleotides 56012 to the Sall site (1.8 kilobases plus the 3.7 kilobases of the vector = 5.5 kilobases) was isolated. In the same ligation, this 5.8-kilobase fragment was ligated with the PCR-amplified products from nucleotides 1-743
20 (EcoRI-XhoI), the CEA gene (XhoI-SnaBI), and the PCR-amplified product containing poliovirus nucleotides 3370 (SnaBI) to 5601 (BglII). After incubation at 15°C overnight, the ligated products were transformed into *Escherichia coli* DH5 α and the colonies were selected on ampicillin-containing plates. Plasmids isolated from individual colonies were screened for the desired insert by restriction enzyme digestion. The final plasmid was designated pT7-
25 IC-CEA-sig⁻.

Cell Culture and Viruses.

HeLa cells were purchased from the American Type Culture Collection and were maintained in monolayer culture in DMEM (GIBCO/BRL) supplemented with 5% fetal
30 bovine serum. BSC-40 cells were maintained in DMEM with 5% fetal bovine serum as described previously (Ansardi, D.A. et al. (1991) *J. Virol.* 65:2088-2092).

The vaccinia viruses used for these studies were grown in TK-143-B cells (American Type Culture Collection) and were concentrated for experimental use as previously described (Ansardi, D.A. et al. (1991) *J. Virol.* 65:2088-2092). The titers of vaccinia virus were
35 determined by plaque assay on BSC-40 cell monolayers. The recombinant vaccinia virus used for the encapsidation experiments (VV-P1) was constructed as described previously (Ansardi, D.A. et al. (1991) *J. Virol.* 65:2088-2092). The recombinant vaccinia virus which expresses the CEA (rV-CEA) has been previously described (Kantor, J. et al. (1992) *J. Natl. Cancer Inst.* 84:1084-1091; Kantor, J. et al. (1992) *Cancer Res.* 52:6917-6925).

In Vitro Transcription, Transfections, and Metabolic Labeling

In vitro transcription was carried out as described previously (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). The *in vitro* transcribed RNA was transfected into HeLa cells with DEAE-dextran (molecular mass, 500 kDa) as a facilitator as described previously (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). The cells were first infected with vaccinia virus for 2 h prior to transfection. After the 2 hour infection period, the cells were washed once with DMEM without methionine-cysteine or leucine (depending on the metabolic label), and incubated in this medium for an additional 45 min to 1 hour. In the case of recombinant poliovirus nucleic acid-infected cells, the infections were allowed to proceed 4-6 hours prior to metabolic labeling. For [³⁵S]methionine-cysteine labelings, the cells were washed once and incubated in DMEM without methionine-cysteine plus [³⁵S]methionine-cysteine (Translabel; ICN) 150 µCi/ml final concentration. In the case of metabolic labeling with [³H]leucine, cells were labeled for 1.5 h using [³H]leucine (Amersham) (350 µCi/ml) in a final volume of 0.2 ml leucine-free DMEM. After the labeling period, the cells were washed once with PBS and processed for radioimmunoprecipitation as described previously (Ansardi, D.A. et al. (1991) *J. Virol.* 65:2088-2092). To detect CEA protein, a CEA-specific monoclonal antibody (Col-1) at a concentration of 3 µg/ml was used.

Encapsidation and Serial Passage of Recombinant poliovirus nucleic acids by VV-P1

Procedures for encapsidation of the recombinant poliovirus nucleic acids have been described previously (Porter, D.C. et al. ((1993) *J. Virol.* 67:3712-2719; Ansardi, D.A. et al. (1993) *J. Virol.* 67:3684-3690). Briefly, HeLa cells were infected with 20 PFUs/cell of VV-P1 for 2 hours. The cells were then transfected with *in vitro* transcribed RNA using DEAE-dextran (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). Sixteen hours after transfection, the cells and medium were harvested by directly adding Triton X-100 to the medium, at a final concentration of 1%. The medium-cell lysate was clarified in a microcentrifuge for 20 min at 14,000 x g. The clarified lysate was treated with 20 µg/ml of RNase A at 37°C for 15 min, then diluted to 4 ml with 30 mM Tris-HCl (pH 8.0, 0.1 M NaCl, 1% Triton X-100), and overlaid on a 0.5 ml-sucrose cushion (30% sucrose, 30mM Tris-HCl pH 8.0, 1M NaCl, 0.1% BSA) in SW 55 tubes. The sucrose cushion was centrifuged at 45,000 rpm for 2 h. Pelleted material was washed with PBS-0.1% BSA and recentrifuged at 45,000 rpm for 2 h. The final pellet was resuspended in 0.6 ml complete medium. BSC-40 cells were infected for 2 hours with 20 PFUs/cell of VV-P1, and 0.25 ml of the 0.6 ml was used to infect cells infected with VV-P1; after 24 hours, the cells and media were harvested. This was designated Pass 1.

For serial passage of the encapsidated recombinant poliovirus nucleic acids, BSC-40 cells were infected with 20 PFUs of VV-P1/cell. At 2 hours posttransfection, the cells were infected with Pass 1 of the encapsidated recombinant poliovirus nucleic acids. The cultures were harvested at 24 hours postinfection by three successive freeze-thaws, sonicated, and

clarified by centrifugation at 14,000 x g for 20 min. The supernatants were stored at -70°C or used immediately for additional passages, following the same procedure.

Estimation of the Titer of Encapsidated Recombinant poliovirus nucleic acids

5 Since the encapsidated recombinant poliovirus nucleic acids have the capacity to infect cells, but lack capsid proteins, they cannot form plaques and therefore virus titers cannot be quantified by traditional assays. To overcome this problem, a method to estimate the titer of the encapsidated recombinant poliovirus nucleic acids by comparison with wild-type poliovirus of known titer (Porter, D.C. et al. ((1993) *J. Virol.* 67:3712-2719; Ansardi, 10 D.A. et al. (1993) *J. Virol.* 67:3684-3690) was used. The resulting titer is then expressed in infectious units of recombinant poliovirus nucleic acids, since the infection of cells with the recombinant poliovirus nucleic acids does not lead to plaque formation due to the absence of P1 capsid genes. It was determined experimentally that the infectivity of equal amounts of infectious units of encapsidated recombinant poliovirus nucleic acids correlates with equal 15 amounts of PFUs of wild-type poliovirus.

Immunization of Mice and Analysis of CEA-Specific Antibody Response

 The encapsidated recombinant poliovirus nucleic acids contain a type I Mahoney capsid. Since the type I strain of poliovirus does not infect mice, transgenic mice (designated 20 as Tg PVR1) which express the receptor for poliovirus and are susceptible to poliovirus and are susceptible to poliovirus infection (Ren, R. et al. (1990) *Cell* 63:353-362) were used. Mice (4-5-week old) were immunized by i.m. infection at monthly intervals with recombinant poliovirus nucleic acids expressing CEA; each mouse received 3 doses containing approximately 3×10^4 infectious units/mouse in 50 μ l sterile PBS. To remove residual VV- 25 P1, the recombinant poliovirus nucleic acid preparations were incubated with anti-vaccinia virus antibodies (Lee Biomolecular, San Diego, CA). The complete removal of residual VV-P1 was confirmed by the lack of vaccinia virus plaques after a 3-day plaque assay. Blood was collected from the tail veins of mice before and at selected times after immunization, centrifuged, and the plasma was collected and frozen until assay. ELISA was used for the 30 determination of antigen-specific antibodies. The assays were performed in 96-well polystyrene microtiter plates (Dynatech, Alexandria, VA) coated with recombinant CEA or whole poliovirus type I at a concentration of 5 and 1 μ g/ml, respectively. The CEA used for these studies was expressed in *E. coli*, using a pET vector with a 6-histidine affinity tag to facilitate purification (Novagen). The majority of the CEA product isolated from the nickel 35 column used for purification was an 80-kDa protein corresponding to the nonglycosylated CEA. The poliovirus type I (Sabin) used was grown in tissue culture cells and purified by centrifugation (Ansardi, D.A. et al. (1993) *J. Virol.* 67:3684-3690). Dilutions of sera were incubated overnight at 4°C on coated and blocked ELISA plates, and the bound immunoglobulins were detected with horseradish peroxidase-labeled antimouse

immunoglobulins (Southern Biotechnology Associates, Birmingham, AL). At the end of the incubation time (3 hours at 37°C), the peroxidase substrate 2,2'-azino-bis-(3-ethylbenzthiazoline) sulfonic acid (Sigma, St. Louis, MO) in citrate buffer (pH 4.2) containing 0.0075% H₂O₂ was added. The color developed was measured in V_{max} kinetic microplate reader (Molecular Devices, Palo Alto, CA) at 414 nm. The results were expressed as absorbance values at a fixed dilution or as end point titration values.

EXAMPLE 7:**CONSTRUCTION OF RECOMBINANT POLIOVIRUS
NUCLEIC ACID CONTAINING THE GENE FOR
CARCINOEMBRYONIC ANTIGEN**

The starting plasmid for the experiments described herein contains the full-length infectious poliovirus cDNA positioned downstream from a phage T7 promoter, designated pT7-IC (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883) (Figure 23A). With reference to Figure 23A, the poliovirus capsid proteins (VP4, VP3, VP2, and VP1) are encoded in the P1 region of the poliovirus genome; the viral proteinase 2A and viral proteins 2B and 2C are encoded in the P2 region; and the viral proteins 3AB, 3C, and 3D (RNA polymerase) are encoded in the P3 region. The relevant restriction sites used for construction of the recombinant poliovirus nucleic acid containing the gene for CEA are indicated. With reference to Figure 23B, which is a schematic of the CEA protein, the signal sequence of the CEA protein consists of 34 amino acids (black box). The signal peptidase cleavage site occurs between the alanine and lysine amino acids. The codon for the carboxyl terminal isoleucine amino acid is followed by a TAA termination codon. Construction of the recombinant poliovirus nucleic acid containing the signal-minus CEA gene occurred as follows: PCR was used to amplify the CEA-gene encoding amino acids from the lysine at the amino terminus of signal-minus CEA to the isoleucine at the COOH terminus of CEA as shown in Figure 23B. To subclone the gene encoding the signal-minus CEA protein, XhoI and SnaBI restriction endonuclease sites were positioned within the PCR primers. The final construct encodes the first two amino acids of the poliovirus P1 protein (Met-Gly) followed by two amino acids, leucine and glutamic acid (encoded by the XhoI restriction site) followed by the lysine amino acid of the signal-minus CEA protein. The CEA gene was positioned so that nine amino acids will be spaced between the C-terminal isoleucine of CEA and the tyrosine-glycine cleavage site for the 2A proteinase; the leucine amino acid required for 2A cleavage is boxed in Figure 23C. This final construct, as shown in Figure 23C, was designated pT7-IC-CEA-sig⁻.

After the pT7-IC plasmid is linearized at the unique SalI restriction site, *in vitro* transcription mediated by phage T7 RNA polymerase is used to generate RNA transcripts for transfection. Transfection of the *in vitro* RNA transcript into tissue culture cells (i.e., HeLa cells) results in translation and replication of the RNA, which leads to production of

infectious poliovirus. It has been found that the infectivity of the RNA derived from this plasmid is in the range of 10^6 PFUs/ μ g transfected RNA (Choi, W.S. et al. (1991) *J. Virol.* 65:2875-2883). Previous studies have found that the majority of the P1 region of the poliovirus cDNA can be deleted without affecting the capacity of the resulting RNA genome to replicate when transfected into cells (Kaplan, G. et al. (1988) *J. Virol.* 62:1687-1696). To extend these studies, it was investigated whether the entire P1 region can be substituted with the 2.4-kilobase cDNA for CEA (Figure 23B; Beauchemin, N. et al. (1987) *Mol. Cell. Biol.* 7:3221-3230; Oikawa, S. et al. (1987) *Biochim. Biophys. Acta.* 142:511-518).

In preliminary studies, it was found that RNA containing full-length CEA was not replication competent. It was possible that the signal sequence (amino acids 1-34) of the CEA protein was directing the CEA-P2-P3 fusion protein to the endoplasmic reticulum and in doing so prevented replication of the RNA. To test this possibility, the CEA gene was engineered to remove the first 34 amino acids of the CEA protein, which has been postulated to be the signal sequence (Oikawa, S. et al. (1987) *Biochim. Biophys. Acta.* 142:511-518; Thompson, J. et al. (1988) *Tumor Biol.* 9:63-83). PCR was used to amplify a region from amino acids 35-688 of the CEA gene that was then subcloned into the poliovirus recombinant poliovirus nucleic acid. The resulting DNA encoded the first two amino acids of the poliovirus P1 protein (Met-Gly) followed by two amino acids (Leu-Glu) derived from the XhoI restriction endonuclease site, followed by amino acid 35 (Lys) of the CEA protein. The isoleucine in CEA was fused to an additional nine amino acids (Tyr-Val-Thr-Lys-Asp-Leu-Thr-Thr-Tyr) in the predicted protein product. In this CEA protein, a leucine residue at the P4 position was included for optimal 2A autocatalytic cleavage (Harris, K.S. et al. (1990) *Semin. Virol.* 1:323-333).

Following *in vitro* transcription of pT7-IC-CEA-sig⁻, the RNA transcripts were transfected into cells previously infected with VV-P1. For these studies five independent clones containing the signal-minus CEA gene (designated as sig⁻ CEA) were tested. As a positive control, a recombinant poliovirus nucleic acid which contains the HIV-1 *gag* gene (corresponding to the capsid, p24 protein) positioned between nucleotides 1174 and 2470 of the poliovirus genome was used. Cells were also infected with poliovirus to serve as a control in these experiments. At 6 hours posttransfection, the cells were metabolically labeled and ³⁵S-labeled proteins were immunoprecipitated with either anti-3D^{pol} (Figure 24A) or anti-CEA (Col-1 monoclonal antibody (Figure 24B)). The immunoprecipitated proteins were separated on SDS-10% polyacrylamide gels, and autoradiograms of these gels were generated (shown in Figures 24A and 24B). Additional sets of cells were either infected with poliovirus (Figure 24A) or a recombinant vaccinia virus which expresses CEA (rV-CEA, Figure 24B) to serve as a source of marker proteins. The origins of the samples in each of the lanes for both Figure 24A and Figure 24B are as follows: Lane 1, mock transfected cells; Lane 2, cells transfected with RNA derived from clone 1 of PT7-IC-CEA-sig⁻; Lane 3, cells transfected with RNA derived from clone 2 of pT7-IC-CEA-sig⁻; Lane 4, cells

transfected with RNA derived from clone 3 of pT7-IC-CEA-sig⁻; Lane 5, cells transfected with RNA derived from clone 4 of pT7-IC-CEA-sig⁻; Lane 6, cells transfected with RNA derived from clone 5 of pT7-IC-CEA-sig⁻; Lane 7, cells transfected with RNA derived from transcription of pT7-IC-Gag1; Lane 8, cells infected with either poliovirus (Figure 24A) or rV-CEA (Figure 24B). The migration of the molecular mass markers is noted. The migration of 3CD (Figure 24A) and glycosylated and unglycosylated forms of CEA (Figure 24B) are also noted.

In contrast to the results with the CEA recombinant poliovirus nucleic acids encoding the signal sequence, the 3CD protein from cells transfected with RNA derived from five individual clones of pT7-IC-CEA-sig⁻ was detected. The levels of 3CD expression in this experiment were comparable to those of cells transfected with RNA derived from *in vitro* transcription of pT7-IC-Gag 1, which was known from previous studies to be replication competent (Porter, D.C. et al. (1993) *J. Virol.* 67:3712-3719; Figure 24A). To determine if the CEA protein was expressed in the transfected cells, the lysates were also incubated with the Col-1 antibody to immunoprecipitate CEA-related proteins (Figure 24B). Since the CEA protein should not be glycosylated, it was expected that the CEA product would be approximately 80 kDa in molecular mass. In each of the transfections with RNA derived the five independent clones, an 80-kDa protein was immunoprecipitated; this protein was not detected in cells transfected with recombinant poliovirus nucleic acids containing the HIV-1 gag gene.

EXAMPLE 8: **ENCAPSIDATION AND SERIAL PASSAGE OF**
RECOMBINANT POLIOVIRUS NUCLEIC ACID
CONTAINING THE GENE FOR
CARCINOEMBRYONIC ANTIGEN

To determine whether the recombinant poliovirus nucleic acids containing the CEA sig⁻ gene could be encapsidated if provided the poliovirus capsid proteins, cells were infected first with VV-P1, followed by transfection with either the RNA derived pT7-IC-CEA-sig⁻ or PT7-IC-Gag 1. A mock transfection was also included as an additional control. At 24 h posttransfection, extracts of the cells were generated by addition of detergents to the culture medium, and poliovirus-like particles were concentrated from the extracts by centrifugation through a 30% sucrose cushion. After resuspension, the concentrated material was used to infect cells that had been infected previously with either wild-type vaccinia virus or VV-P1 (passage 1). This coinfection was allowed to proceed overnight, after which extracts of the cells were generated by repeated freezing and thawing. The freeze-thaw extracts were clarified and used to repeat the coinfection procedure. This process was repeated for an additional nine serial passages to generate stocks of the encapsidated recombinant poliovirus nucleic acids. For the experiment shown in Figures 25A-C, the lysates from Pass 10 material

were used to infect BSC-40 cells. At 6.5 hours postinfection, the cells were starved for 30 min in methionine-cysteine-free DMEM, and then were metabolically labeled for an additional 90 min. The cell lysates were then analyzed by immunoprecipitation with either anti-3D^{pol} antibody (Figure 25A) or antibody to the CEA protein (Col-1, Figure 25B). The origins of the samples in the lanes for Figures 25A and 25B are as follows: Lane 1, cells that were infected with wild-type vaccinia virus and then mock-transfected; Lane 2, cells that were infected with VV-P1 and then mock-transfected; Lane 3, cells that were infected with wild-type vaccinia virus and then transfected with RNA derived from *in vitro* transcription of pT7-IC-CEA-sig⁻; Lane 4, cells that were infected with VV-P1 and then transfected with RNA derived from pT7-IC-CEA-sig⁻; Lane 5, cells that were infected with wild-type vaccinia virus and then transfected with RNA derived from pT7-IC-CEA-sig⁻ (a second independent clone); Lane 6, cells were infected with VV-P1 and then transfected with RNA derived from pT7-IC-CEA-sig⁻ (a second independent clone); Lane 7, cells that were infected with wild-type vaccinia virus and then transfected with RNA derived from *in vitro* transcription of pT7-IC-Gag 1; Lane 8, cells that were infected with VV-P1 and then transfected with RNA derived from *in vitro* transcription of pT7-IC-Gag 1; Lane 9, cells that were infected with poliovirus (Figure 25A) or recombinant vaccinia virus CEA (rV-CEA, Figure 25B). The migration of the molecular mass markers is noted. In Figure 25A, the migration of 3CD protein is noted, whereas in Figure 25B, the migrations of the glycosylated (*gly*) and nonglycosylated (sig⁻) forms of CEA are noted. Arrows note the position of the anti-CEA immunoreactive proteins of larger molecular mass observed in cells infected with encapsidated poliovirus nucleic acid containing the signal-minus CEA gene. In Figure 25C, cells were infected with a Pass 20 stock of encapsidated recombinant poliovirus nucleic acid containing the signal-minus CEA gene and then metabolically labeled with [³H]leucine. The origins of the samples in the lanes for Figure 25C are as follows: Lane 1 includes uninfected cells metabolically labeled, followed by immunoprecipitation with Col-1 antibody; Lane 2, cells infected with encapsidated recombinant poliovirus nucleic acid containing the signal-minus CEA gene, followed by immunoprecipitation with Col-1 antibody. The molecular mass standards are noted as well as the migration of glycosylated CEA (*glyc.*), nonglycosylated CEA (sig⁻), and breakdown product (asterisk).

No expression of 3CD proteins was detected upon infection of cells with the sample originating from the mock-transfected cells and serially passaged 10 times with either wild-type vaccinia virus or VV-P1 (Figure 25A). From analysis of 3CD expression, it was concluded that RNA derived from transcription of pT7-IC-CEA-sig⁻ was encapsidated when passaged in the presence of VV-P1, but not in the presence of wild-type vaccinia virus.

To determine if the CEA protein was expressed from the encapsidated recombinant poliovirus nucleic acids, the extracts from infected cells that had been metabolically labeled followed by immunoprecipitation with the Col-1 antibody (Figure 25B) were analyzed. Again, in samples from mock-transfected cells that had been subsequently passaged in the

presence of either wild-type vaccinia virus or VV-P1, no immunoreactive protein was detected. A protein of molecular mass 80 kDa was immunoprecipitated from cells infected with the extracts originating from cells transfected with the RNA derived from pT7-IC-CEA sig⁻ which has been passaged in the presence of VV-P1, but not in the presence of wild-type virus. As expected, no Col-1 immunoreactive material was detected in cells infected with the RNA derived from pT7-IC-Gag 1, although this RNA was encapsidated in cells in the presence of VV-P1 (Figure 25A).

Although the majority of the CEA protein immunoprecipitated from the cells infected with either stock of the encapsidated recombinant poliovirus RNA was the 80-kDa protein corresponding to the expected molecular mass of unglycosylated CEA, it was noted there was a small amount of protein immunoprecipitated corresponding to the molecular mass for the fully glycosylated CEA protein (180 kDa). To further explore this result, a concentrated stock of the signal-minus CEA recombinant poliovirus nucleic acid that had been passaged an additional 10 times (20 serial passages in all) and concentrated by pelleting through a 30% sucrose cushion prior to use in these experiments was used. Cells were infected with the encapsidated recombinant poliovirus nucleic acids, followed by metabolic radiolabeling for 1.5 h with [³H]leucine since CEA contains more leucine amino acids than methionine or cysteine (Oikawa, S. et al. (1987) *Biochim. Biophys. Acta.* 142:511-518). This should increase the sensitivity of detection of the higher molecular mass CEA proteins. Three proteins were immunoprecipitated using the Col-1 antibody from [³H]leucine-labeled cells infected with the stock of the encapsidated recombinant poliovirus nucleic acid (Figure 25C). One of these proteins corresponded to the unglycosylated protein of a smaller molecular mass of approximately 80 kDa, while a protein of a smaller molecular mass, corresponding to approximately 52 kDa, was also immunoprecipitated. This protein is believed to represent a breakdown product of the CEA protein that was not detected previously because of the relatively few methionine or cysteine amino acids found in the CEA protein. A third protein of approximately 180 kDa was also immunoprecipitated, suggesting that glycosylated CEA protein might be produced in cells infected with the encapsidated recombinant poliovirus nucleic acids at low levels.

EXAMPLE 9:

PRODUCTION OF ANTI-POLIOVIRUS AND ANTI-CARCINOEMBRYONIC ANTIGEN ANTIBODIES IN MICE IMMUNIZED WITH ENCAPSIDATED RECOMBINANT POLIOVIRUS NUCLEIC ACID CONTAINING THE GENE FOR CARCINOEMBRYONIC ANTIGEN

To evaluate the immunogenicity of the encapsidated recombinant poliovirus nucleic acids which express the CEA protein, transgenic mice that express the receptor for poliovirus

and are susceptible to infection with poliovirus were used (Ren, R. et al. (1990) *Cell* 63:353-362). The mice were bred in a germ-free environment until use in the experiments. The four mice used in the experiment were bled prior to i.m. immunization with approximately 10^4 infectious units of the encapsidated recombinant poliovirus nucleic acid which expresses CEA. The serum samples from the mice at each of the pre- and postimmune time points were pooled and assayed using a solid-phase ELISA with whole poliovirus or recombinant CEA expressed in *E. coli* as the coating solution. The results are presented as absorbance 414-nm values at a fixed dilution and as end point titration values for anti-CEA (Figure 26A) and antipoliovirus (Figure 26B). By 28 days after the second booster immunization, a pronounced CEA-specific antibody response was detected as measured by the ELISA assay. The end point titer had increased from 1:25 (preimmune) to 1:6400 (Figure 26A). A similar increase was observed in the antipoliovirus in the serum samples (Figure 26B). As a control, no increase in anti-CEA antibodies in the sera from mice immunized with the recombinant poliovirus nucleic acid expressing HIV-1 Gag was found. Taken together, these results demonstrate that the recombinant poliovirus nucleic acids infect cells, presumably the muscle myofibers at the site of injection, and express sufficient amounts of CEA to stimulate an anti-CEA antibody response.

The construction and characterization of RNA recombinant poliovirus nucleic acids which express the CEA protein when infected is described herein. A recombinant poliovirus nucleic acid encoding the signal-minus CEA protein was replication competent and expressed nonglycosylated CEA protein when transfected into cells. Using the methods of encapsidating recombinant poliovirus nucleic acids described herein, stocks of encapsidated recombinant poliovirus nucleic acids containing the signal-minus CEA gene were generated. The use of encapsidated poliovirus recombinant poliovirus nucleic acids as a vaccine vehicle has several distinguishing features: (a) this is one of the few vector systems based entirely on an RNA virus. Since poliovirus replication does not involve DNA intermediates, in contrast to retroviruses, the possibility of recombination in the host cell DNA is virtually eliminated; (b) infection of cells with encapsidated recombinant poliovirus nucleic acids results in an amplification of the recombinant poliovirus nucleic acid RNA and preferential expression of the foreign gene over cellular gene products since poliovirus has evolved mechanisms to promote the synthesis of its own viral proteins (Ehrenfeld, E. et al. (1982) *Cell* 28:435-436); and (c) the encapsidated poliovirus recombinant poliovirus nucleic acids are noninfectious because they do not encode the viral P1 capsid proteins. The recombinant poliovirus nucleic acid requires capsid proteins to be propagated and transmitted from cell to cell. Infection of cells or an animal with the encapsidated recombinant poliovirus nucleic acids alone then results in a single round of infection without a chance for further spread. Because of this feature, the encapsidated recombinant poliovirus nucleic acids can be exploited to deliver nucleic acids to cells without risk of viral spread.

Equivalents

Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.

5

All referenced patents and publications are hereby incorporated by reference in their entirety.

What is claimed is:

Gln Lys Leu Leu Asp Thr Tyr Gly Ala Gln
1 5 10

1. A method for encapsidating a recombinant poliovirus nucleic acid, comprising the steps of:

5 (a) providing a recombinant poliovirus nucleic acid which lacks the entire P1 capsid precursor region of the poliovirus genome and an expression vector lacking an infectious poliovirus genome, the nucleic acid of which encodes poliovirus P1 capsid precursor protein and directs expression of the poliovirus P1 capsid precursor protein;

10 (b) contacting a host cell with the recombinant poliovirus nucleic acid and the expression vector under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the expression vector into the host cell; and

15 (c) obtaining a yield of encapsidated viruses which substantially comprises encapsidated recombinant poliovirus nucleic acid.

2. The method of claim 1 wherein the expression vector is introduced into the host cell prior to the introduction of the recombinant poliovirus nucleic acid.

20 3. The method of claim 1 wherein the recombinant poliovirus nucleic acid is derived from a poliovirus serotype selected from the group consisting of poliovirus type I, poliovirus type II, and poliovirus type III.

25 4. The method of claim 1 wherein the nucleotide sequence of the recombinant poliovirus nucleic acid which encodes the P1 capsid precursor protein is replaced by a foreign nucleotide sequence encoding, in an expressible form, a foreign protein or fragment thereof.

30 5. The method of claim 4 wherein the foreign nucleotide sequence is flanked by a first nucleotide sequence and a second nucleotide sequence each of which encodes a cleavage site for a poliovirus enzyme.

6. The method of claim 5 wherein the cleavage site is a cleavage site for poliovirus 2A protease.

35 7. The method of claim 1 wherein the expression vector comprises a virus.

8. The method of claim 7 wherein the virus is a recombinant vaccinia virus.

9. The method of claim 8 wherein the nucleic acid of the recombinant vaccinia virus encodes the poliovirus P1 capsid precursor protein and directs expression of a nucleotide sequence encoding the poliovirus P1 capsid precursor protein.

5 10. The method of claim 1 wherein the expression vector comprises a plasmid.

11. The method of claim 5 wherein the foreign nucleotide sequence is selected from the group consisting of the *gag* gene, the *pol* gene, and the *env* gene of human immunodeficiency virus type 1.

10

12. The method of claim 11 wherein the foreign nucleotide sequence is the *gag* gene of human immunodeficiency virus type 1.

13. The method of claim 12 further comprising a nucleotide sequence encoding at
15 least two amino acids at the N-terminus of the *gag* protein of human immunodeficiency virus type 1 and at least two amino acids at the C-terminus of the *gag* protein of human immunodeficiency virus type 1 which comprise a cleavage site for poliovirus 2A protease.

14. The method of claim 13 wherein the nucleotide sequence encodes the
20 following amino acids at the N-terminus of the *gag* protein of human immunodeficiency virus type 1:

Gln-Lys-Leu-Leu-Asp-Thr-Tyr-Gly-Ala-Gln (SEQ ID NO: 24)

15. The method of claim 13 wherein the nucleotide sequence encodes the
25 following amino acids at the C-terminus of the *gag* protein of human immunodeficiency virus type 1:

Thr-Lys-Asp-Leu-Thr-Thr-Tyr-Gly (SEQ ID NO: 15)

30

16. The method of claim 5 wherein the foreign nucleotide sequence encodes a human tumor-associated antigen.

17. The method of claim 16 wherein the human tumor-associated antigen is
35 carcinoembryonic antigen.

18. The method of claim 17 wherein the nucleotide sequence encoding carcinoembryonic antigen does not encode a signal sequence.

19. The method of claim 17 further comprising a nucleotide sequence encoding at least two amino acids at the N-terminus of the carcinoembryonic antigen and at least two amino acids at the C-terminus of the carcinoembryonic antigen which comprise a cleavage site for poliovirus 2A protease.

5

20. The method of claim 16 wherein the nucleotide sequence encodes the following amino acids at the C-terminus of the carcinoembryonic antigen:

Thr-Lys-Asp-Leu-Thr-Thr-Tyr-Gly (SEQ ID NO: 15)

10

21. The method of claim 1 wherein the host cell is a mammalian host cell.

22. A method for encapsidating a recombinant poliovirus nucleic acid, comprising the steps of:

15

(a) providing a recombinant poliovirus nucleic acid which lacks the entire P1 capsid precursor region of the poliovirus genome and a recombinant vaccinia virus, the nucleic acid of which encodes poliovirus P1 capsid precursor protein and directs expression of the poliovirus P1 capsid precursor protein; and

20

(b) contacting a mammalian host cell with the recombinant poliovirus nucleic acid and the recombinant vaccinia virus under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the recombinant vaccinia virus into the mammalian host cell; and

25

(c) obtaining a yield of encapsidated viruses which substantially comprises encapsidated recombinant poliovirus nucleic acid.

23. The method of claim 22 wherein the nucleotide sequence of the recombinant poliovirus nucleic acid which encodes the P1 capsid precursor protein is replaced by a foreign nucleotide sequence encoding, in an expressible form, a foreign protein or fragment thereof.

30

24. The method of claim 23 wherein the foreign nucleotide sequence is flanked by a first nucleotide sequence and a second nucleotide sequence each of which encodes a cleavage site for a poliovirus enzyme.

35

25. The method of claim 24 wherein the cleavage site is a cleavage site for poliovirus 2A protease.

26. The method of claim 23 wherein the foreign nucleotide sequence is selected from the group consisting of the *gag* gene, the *pol* gene, and the *env* gene of human immunodeficiency virus type 1.

5 27. The method of claim 26 wherein the foreign nucleotide sequence is the *gag* gene of human immunodeficiency virus type 1.

28. An encapsidated recombinant poliovirus nucleic acid produced by the method of claim 5.

10

29. An encapsidated recombinant poliovirus nucleic acid produced by the method of claim 24.

30. An encapsidated recombinant poliovirus nucleic acid which lacks the
15 nucleotide sequence encoding the entire P1 capsid precursor region of the poliovirus genome, the encapsidated recombinant poliovirus nucleic acid being substantially free of nucleic acid which encodes and directs expression of the entire P1 capsid precursor region which is lacking in the encapsidated recombinant poliovirus nucleic acid.

20 31. The encapsidated recombinant poliovirus nucleic acid of claim 30. which is ribonucleic acid.

32. The encapsidated recombinant poliovirus nucleic acid of claim 30. which is
25 selected from the group consisting of poliovirus type I, poliovirus type II, and poliovirus type III.

33. The encapsidated recombinant poliovirus nucleic acid of claim 30. wherein the
nucleotide sequence of the recombinant poliovirus nucleic acid which encodes the entire
poliovirus capsid P1 precursor region is replaced by a foreign nucleotide sequence encoding,
30 in an expressible form, a foreign protein or fragment thereof.

34. The method of claim 33 wherein the foreign nucleotide sequence is flanked by
a first nucleotide sequence and a second nucleotide sequence each of which encodes a
cleavage site for a poliovirus enzyme.

35

35. The method of claim 34 wherein the cleavage site is a cleavage site for poliovirus 2A protease.

36. The encapsidated recombinant poliovirus nucleic acid of claim 33, wherein the foreign nucleotide sequence encodes a protein or fragment thereof selected from the group consisting of viral antigens or fragments thereof, bacterial antigens or fragments thereof, tumor antigens or fragments thereof, immunological response modifiers or fragments thereof, and proteins or RNA with enzymatic activity or fragments thereof.

37. The encapsidated recombinant poliovirus nucleic acid of claim 36, wherein the viral antigen is an human immunodeficiency virus antigen.

38. The encapsidated recombinant poliovirus nucleic acid of claim 37, wherein the human immunodeficiency virus antigen is selected from the group consisting of the *gag* protein or a fragment thereof, the *pol* protein or a fragment thereof, and the *env* protein or a fragment thereof.

39. The encapsidated recombinant poliovirus nucleic acid of claim 36, wherein the RNA with enzymatic activity is a ribozyme.

40. The encapsidated recombinant poliovirus nucleic acid of claim 36, wherein the foreign nucleotide sequence encodes an antisense nucleic acid.

41. The encapsidated recombinant poliovirus nucleic acid of claim 34, wherein the nucleic acid which encodes and directs expression of the entire P1 capsid precursor protein is in the form of encapsidated poliovirus nucleic acid which encodes and directs expression the entire P1 capsid precursor protein.

42. The encapsidated recombinant poliovirus nucleic acid of claim 34, wherein the nucleic acid which encodes and directs expression of the entire P1 capsid precursor protein is in the form of a vector having an infectious poliovirus genome.

43. A recombinant poliovirus nucleic acid wherein the nucleotide sequence encoding the entire P1 capsid precursor region of the poliovirus genome is replaced with a foreign nucleotide sequence.

44. The recombinant poliovirus nucleic acid of claim 43, which is ribonucleic acid.

45. The recombinant poliovirus nucleic acid of claim 43 wherein the foreign nucleotide sequence is flanked by a first nucleotide sequence and a second nucleotide sequence each of which encodes a cleavage site for a poliovirus enzyme.

46. The recombinant poliovirus nucleic acid of claim 45 wherein the cleavage site is a cleavage site for poliovirus 2A protease.

5 47. A vaccine composition comprising the encapsidated recombinant poliovirus nucleic acid of claim 34 and a physiologically acceptable carrier.

48. A vaccine composition comprising the encapsidated recombinant poliovirus nucleic acid of claim 41 and a physiologically acceptable carrier.

10

49. A vaccine composition comprising the encapsidated recombinant poliovirus nucleic acid of claim 42 and a physiologically acceptable carrier.

50. A vaccine composition comprising the recombinant poliovirus nucleic acid of claim 45 and a physiologically acceptable carrier.

15

51. A method for stimulating an immune response to a protein or fragment thereof, in a subject, comprising
administering, in a physiologically acceptable carrier, an effective amount of a
composition comprising a recombinant poliovirus nucleic acid having a foreign nucleotide
sequence encoding, in an expressible form, an immunogenic protein or fragment thereof
substituted for the entire P1 capsid precursor region of the poliovirus genome.

20

52. The method of claim 51 wherein the recombinant poliovirus nucleic acid is encapsidated.

25

53. The method of claim 51 wherein the foreign nucleotide sequence is flanked by a first nucleotide sequence and a second nucleotide sequence each of which encodes a cleavage site for a poliovirus enzyme.

30

54. The method of claim 53 wherein the cleavage site is a cleavage site for poliovirus 2A protease.

55. The method of claim 51 wherein the composition is administered orally or by intramuscular injections.

35

56. The method of claim 51 wherein the protein or fragment thereof is a human immunodeficiency virus type 1 protein or fragment thereof.

57. The method of claim 56 wherein the human immunodeficiency virus type 1 protein or fragment thereof is selected from the group consisting of the *gag* protein, the *pol* protein, and the *env* protein of human immunodeficiency virus type 1.

5 58. The method of claim 51 wherein the protein or fragment thereof is a tumor-associated antigen or fragment thereof.

59. A method for stimulating an immune response to a foreign protein, or fragment thereof, in a subject, comprising the steps of:

- 10 (a) removing host cells from the subject; and
(b) contacting the host cells with
(i) a recombinant poliovirus nucleic acid having a foreign nucleotide sequence substituted for the entire P1 capsid precursor region of the poliovirus genome; and
(ii) an expression vector lacking an infectious poliovirus genome, the
15 nucleic acid of which encodes poliovirus P1 capsid precursor protein and directs expression of the P1 capsid precursor protein; and
(c) maintaining the cultured host cells under conditions appropriate for introduction of the recombinant poliovirus nucleic acid and the expression vector into the host cells, thereby generating modified host cells which express a foreign protein or fragment
20 thereof encoded by the foreign nucleotide sequence; and
(d) reintroducing the modified host cells into the subject.

INTERNATIONAL SEARCH REPORT

 International application No.
 PCT/US96/01895

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : Please See Extra Sheet.

US CL : Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 514/44; 424/185.1, 188.1, 217.1; 435/69.1, 69.3, 70.3, 91.21, 320.1; 530/826; 536/23.72; 935//32

 Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched
 NONE

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

 APS, MEDLINE
 MORROW CD, PORTER DC, RECOMBINANT POLIOVIRUS

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US96/01895

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☒ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
1-58
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐

The additional search fees were accompanied by the applicant's protest.

☒

No protest accompanied the payment of additional search fees.

A. CLASSIFICATION OF SUBJECT MATTER:

US CL :

514/44; 424/185.1, 188.1, 217.1; 435/69.1, 69.3, 70.3, 91.21, 320.1; 530/826; 536/23.72; 935//32

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claim(s) 1-46, drawn to methods of encapsidating poliovirus nucleic acid and to the product, encapsidated poliovirus.

Group II, claim(s) 47-58, drawn to vaccines and methods of stimulating an immune response using poliovirus.

Group III, claim(s) 59, drawn to methods of stimulating an immune response using modified host cells.

The inventions listed as Groups I-III do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: The claims to the methods of making a first product of Group I are unrelated as a method to the methods of stimulating an immune response or vaccines of Groups II and III. In particular, Group I is drawn to a first appearing method of making a product and the product produced by that method. Group II is drawn to methods which are unrelated to the methods of Group I and therefore share no special technical feature. Likewise, Group III is drawn to a method unrelated to the methods of Group I or Group II, and uses a product which is not shared by either of these other groups. PCT Rules 13.1 and 13.2 do not provide for multiple distinct products and methods within a general inventive concept; see also PCT Article 17(3)(a).
